Fifth Rwanda Population and Housing Census, 2022

Thematic Report
DATA QUALITY ASSESSMENT

July 2023

The National Institute of Statistics of Rwanda (NISR) implemented the Fifth Rwanda Population and Housing Census 2022 (RPHC 2022). Fieldwork was conducted from August 16th to 30th, 2022.

Additional information about the 2022 RPHC may be obtained from the NISR:
P.O. Box 6139, Kigali, Rwanda; Telephone: (+250) 788 383 103/Toll free: 4321

FOREWORD

The Government of Rwanda, through the National Institute of Statistics of Rwanda (NISR), conducted the Fifth Rwanda Population and Housing Census in August 2022. The Census results provide updated demographic, social and economic indicators for policy formulation and planning to support the national development agenda. Census results will also help in tracking the implementation of national, regional, continental and global development goals, such as the National Strategy for Transformation (NST), the AU Agenda 2063, and the Sustainable Development Goals (SDGs).

The Population and Housing Census in Rwanda dates back to the year 1978 when the first ever-modern census was implemented. The second, third, and fourth censuses were carried out in 1991, 2002, and 2012 respectively. The 2022 Rwanda Population and Housing Census marks therefore the fifth in the series following the United Nations Recommendations to conduct a census every ten years.

Considering census' crucial importance for the planning process, the Government of Rwanda has made the Population and Housing Census a priority to be undertaken every 10 years and adopted the use of technologies for timely delivery of census results for use.

Results of the 2022 Population and Housing Census provide population numbers from national to the lowest administrative level, as well as demographic and socio-economic indicators at both national and district levels. The census remains the only national data collection exercise that can provide the lowest levels of disaggregation to support decentralised decision making across the country.

I would like, therefore, to take this opportunity to thank all stakeholders that contributed to the success of the 2022 Rwanda Population and Housing Census. They include Ministries and other Government institutions, international organizations such as the World Bank (WB), the European Union (EU), the United Nations Population Fund (UNFPA), One-UN, UN Women, UNICEF, UNECA, the United Kingdom AID (UKAID), ONS, the African Development Bank (AfDB), the USAID, ENABEL, PARIS 21 and others for their support in diverse ways.

My special thanks go to the local government leaders from the province to the village levels who contributed a lot to the success of the 2022 Rwanda Population and Housing Census. Exceptional gratitude goes also to all enumerators and all field personnel, who collected the information and all respondents for their cooperation and dedication. The National Institute of Statistics of Rwanda (NISR) deserves special appreciation for the excellent operational and coordination of all census activities.

I finally recommend that the invaluable information contained in the different thematic reports of the 5th Rwanda Population and Housing Census be used as updated evidence for all decision and policy making for the national, regional and global development programs.

Dr. Uzziel NDAGIJIMANA
Minister of Finance and Economic Planning

ACKNOWLEDGEMENTS

The National Institute of Statistics of Rwanda (NISR) is pleased to release the results of the Fifth Rwanda Population and Housing Census (RPHC5). The execution of different Census phases: preparatory works, data collection, data processing, tabulation and data analysis; spans for a period of about four years between 2020 and 2023.

NISR has produced several thematic reports to be of direct help to policy makers, planners, local authorities and other census users. The reports provide key information, mainly population size and distribution, education, settlement, population of particular interest (children, youth, women, elderly, etc.), and population projections to mention but a few. NISR expects that results from these reports supplemented by the district profile reports will meet the demand of census data users across board.

On this occasion, I would like to extend my sincere gratitude to the Government of Rwanda and development partners for availing financial, logistical and technical support to the 2022 RPHC. The NISR would like to appreciate all stakeholders who worked tirelessly with us to ensure that the 2022 Rwanda Population and Housing Census operation was successful.

Special recognition also goes to the Ministry of Finance and Economic Planning, Ministry of Defence, Ministry of Local Government, Ministry of Education, Ministry of Foreign Affairs, Ministry of ICT and Innovation, Ministry of Interior, Ministry of Health, Ministry in Charge of Emergency Management, the Rwanda National Police, Rwanda Correctional Services, Rwanda Biomedical Center (RBC), Rwanda Information Society Authority (RISA), Rwanda Utilities Regulatory Authority (RURA), Rwanda Public Procurement Authority (RPPA), Office of Government Spokesperson (OGS), and Rwanda Broadcasting Agency (RBA) for their direct involvement in awareness campaign, logistical and data collection operations.

I also wish to express my appreciation to the local government authorities and NISR staff for their excellent operational organization and to the tens of thousands of enumerators and supervisors for their painstaking efforts throughout the data collection phase.

Finally, to the people of Rwanda, residents, and visitors, your cooperation was crucial towards the success of the census.

Thank you.

MURANGWA Yusuf
Director General,
National Institute of Statistics of Rwanda

EXECUTIVE SUMMARY

Provision of timely and good-quality data, such as census, is essential for socio-economic planning. The standard and global best practice in data production is to assess different phases of census enumeration with a view to ascertaining the quality of its final output. Thus, this report presents the quality review of the 2022 Population and Housing Census, which is the fifth to be conducted in Rwanda (RPHC5). An evaluation of different phases of the census (i.e., the pre-enumeration, enumeration and post-enumeration phases), as well as the assessment of selected key demographic and socio-economic variables are presented in the report. In summary, the quality assessment done shows that every phase of the census was well planned and meticulously implemented. Several quality assurance measures employed at different phases, including the pilot census, training of enumerators, use of CAPI for the enumeration amongst others, greatly enhanced the quality of the census database. Further, the use of modern technologies at different stages of the census greatly contributed to the overall quality of RPHC5. Despite the strong quality assurance measures put in place, a few data quality issues were identified. Notwithstanding, the overall conclusion of the assessment is that the RPHC5 was implemented with strong quality control and gives an excellent representation of the population of Rwanda with generally good measurement of its size, composition, structure, and distribution. Assessment of some selected key demographic and socio-economic characteristics also confirmed that these variables are of high quality.

Specifically, the Post-Enumeration Survey (PES) confirms that the RPHC5 has a good representation and high coverage, with a net-coverage rate of 98.7% nationally, and with little variation across provinces, rural-urban areas and by age and sex. Gross under-coverage rate was 1.51% while gross over-coverage rate (erroneous inclusions) was 0.19%. The PES data that indicates excellent representation is consistent with the plausible growth rate for the population over the inter-censal period implied by the census data.

Evaluation of some key demographic variables such as age, sex, migration flow, in the fertility, mortality, and migration data; as well as the assessment of some selected socio-economic indicators confirmed the high quality of the RPHC5. Importantly, triangulation of the selected variables with other data sources confirmed the good quality of the RPHC5 data in terms of representation of the population across provinces. However, some quality issues were identified on a few population characteristics. These include age heaping, particularly for ages with terminal digits zero and five. However, summary measures from Whipple's, and Myers' indices and the UN joint scores indicate comparatively some improvement and reduction in age heaping in the 2022 Census compared to the 2012 Census. Overall, age heaping disappeared in the population pyramid and line graph based on grouped age data, thus indicating that avoidance of age in preference for another largely occurred within the same five-year age group. In addition, there is strong evidence that the current births and lifetime fertility from the 2022 Census are of high quality. There is, however, some evidence of underreporting of births at the younger ages of mothers, particularly ages 10-19. Further, there is some evidence of under-reporting of infant deaths, and across other ages, hence, the indirect methods are recommended and utilized for estimating mortality rates. In addition, some key socio-economic variables such as marital status, migration, education and life expectancy are considered for evaluation. Evidence from the assessment shows plausible numbers and high quality of reporting for these characteristics.

In conclusion, there are no major quality issues identified in the 2022 Rwanda Population and Housing Census, except some economic activity variables with low quality reporting including the identification of unemployed people. The evaluation of key demographic and socio-economic variables as well as the triangulation of the data with other sources generally confirm the excellent quality of the RPHC5. Thus, the final database of the 2022 Rwanda Population and Housing Census is of high quality.

CHAPTER 1: OVERVIEW OF THE FIFTH RWANDA POPULATION AND HOUSING CENSUS

1.1. Context and justification

The history of the Population and Housing Census in Rwanda dates back in the 1970s. To date, five modern censuses have been successfully conducted in Rwanda: 1978, 1991, 2002, 2012 and 2022.

In line with the United Nations Decennial Census Programme, the 2022 Census is the Fifth Rwanda Population and Housing Census (RPHC5) in series.

Since 2000, and following the endorsement of recommendations from major international conferences held under the auspices of the United Nations, the Government of Rwanda (GoR) has been focusing on the long-term Vision 2020 that aims at transforming Rwanda into a middle-income country. Rwanda pursued the Millennium Development Goals (2000-2015) on the international scene and currently seeks to achieve the Sustainable Development Goals (SDGs) as well as Rwanda's Vision 2050. These goals have been implemented through the medium-term planning framework of the Economic Development

and Poverty Reduction Strategy (EDPRS) and the National Strategy for Transformation (NST1). The measurement of progress in implementing national and international programmes in line with various AU and UN recommendations calls for availability of updated demographic and socio-economic statistical data to inform selected indicators at different levels.

The RPHC5 is a reliable and comprehensive source of such data. It was implemented in a way that allows the disaggregation of indicators at the lowest geographical level where it is applicable. The RPHC5 was undertaken to update the national mapping and demographic databases, to provide indicators for monitoring poverty reduction strategies and achievement of national, regional, and international development goals (NST1, Vision 2050, AU Agenda 2063, SDGs, etc.) and to strengthen the technical capacity of the National Institute of Statistics of Rwanda (NISR).

1.2. Legal and institutional frameworks

As an essential precondition for Census execution, the legislation of its operations was secured by the law No. 53bis/2013 of 28/06/2013 establishing the National Institute of Statistics of Rwanda and determining its mission, organization and functioning; and law No. 45/2013 of 16/06/2013 on the organization of statistical activities in Rwanda.

In order to ensure focused functioning during the whole period of Census execution, a Census Unit of NISR coordinated the overall implementation of the 2022 RPHC5 with support from other NISR units.

1.3. Objectives of the Census

The overall goal of the Fifth Rwanda Population and Housing Census (PHC5) is to contribute to the improvement of the quality of life of the Rwanda population by furnishing the Government and other stakeholders with relevant, reliable, and timely data and information for development planning, policy formulation and service delivery as well as for monitoring and evaluation of development programmes.

Specifically, the 2022 Rwanda Population and Housing Census has been implemented and is well placed to:

- Have increased availability and accessibility of accurate, timely and reliable data on demographic and socio-economic characteristics for evidence-based decisions, policy formulation and monitoring and evaluation of development frameworks at national, sub-national and sectoral levels;

- Have increased knowledge of stakeholders, at all levels, on population characteristics, patterns and trends;
- Have increased utilization, at all levels, of data and information for designing, monitoring and evaluating development programmes; and
- Have strengthened national capacities in data collection, processing, analysis, dissemination and utilization, including geographic information system (GIS).

1.4. Census phases and Methodology

1.4.1. Census phases

Following the preparatory phase of the Census, which consisted of the production of the project document detailing all activities, schedule and Census budget, the following technical activities were undertaken:

- Census mapping conducted between 18th October, 2020 to 15th July, 2021;
- A Pilot Census conducted between 16-30 September, 2021;
- Questionnaire and manual development;
- Census publicity and sensitization campaign;
- Recruitment and training of field staff;
- Census enumeration conducted between 16 -30 August, 2022;

- Post Enumeration Survey conducted between 16-30 September, 2022; and
- Post-census activities, including analysis and dissemination of census results.

The success of the RPHC5 is widely attributable to the rigorous pre-census planning and robust census enumeration monitoring undertaken by the NISR as well as the remarkable support received from the Government, people of Rwanda and the generous technical and financial assistance from international development partners.

1.4.2. Census methodology

1. Census mapping

Census mapping was a crucial phase of the 2022 RPHC. The purpose of the census mapping is to divide the whole country into well-delineated enumeration areas that constitute the smallest operational census units to be assigned to each enumerator during the enumeration period.

The mapping used the latest versions of technology including satellite imagery and ArcGIS software to collect and document detailed information about the administrative units of the country, including boundaries, and locations of major social GPS coordinates of housing units and economic infrastructure (schools, health centres, hospitals, markets, administrative offices, etc.). These activities were carried out together with the estimation of the population and were used for delimitation of enumeration areas (EAs) in all villages (Imidugudu) of the country.

The Census mapping operation lasted for about 9 months (from 18th October, 2020 to 15th July, 2021), which enabled the NISR to better estimate the

number of staff to be recruited (e.g., enumerators, team leaders, supervisors, etc.) and all logistics for the main field data collection. Details from the Census mapping also provided guidance for adequate planning of the other census infrastructures and facilities required for field activities.

The outcomes of the Census mapping included the production of a new sampling frame for future surveys and an updated administrative area boundary map for Rwanda. In total, the country was delineated into 24,339 enumeration areas within the current boundaries of administrative units, consisting of five provinces, 30 districts, 416 sectors and 2,148 cells and 14, 436 villages. This allows for easy compilation of census results in these administrative entities.

2. Pilot Census

Prior to the RPHC5, a pilot census was designed for testing the census questionnaires, other census data-collection tools, enumeration time requirements and

the state-of-preparedness of the entire field work organisation of the census.

The pilot census was conducted from 16th to 30th September, 2021 on a sample of 600 EAs, including 416 randomly selected EAs across all sectors and 184 purposively selected EAs in the areas bordering neighbouring countries to Rwanda and in remote rural areas in order to test the internet connectivity, data transmission, and the availability of electricity. The pilot census was initially planned for 16th to 30th August, 2021 just to fall one year before the main census but was postponed for one month to ensure adequate preventive measures against the spread of Covid-19.

The pilot census was a rehearsal for the actual census enumeration during which the various methods and procedures for field organisation and operations as well as the census publicity/awareness campaign, census maps production, field remote monitoring, data transmission and storage, ICT infrastructure, and data analysis were tested.

The lessons learnt from the pilot census exercise were used to revise some census procedures and instruments to ensure a smooth/successful implementation of the actual census enumeration.

3. Questionnaires and manuals

The questionnaires' design for the 2022 RPHC consisted of updating the questionnaires used during the 2012 census coupled with consultations with stakeholders such as planners and policymakers from different sectors, ministries, other government institutions, private sector, and government's stakeholders,... in order to collect their needs in terms of statistical data. After the development of the questionnaires and the instruction manual, the team of analysts developed a questionnaire specifications to support and ensure a smooth translation of the paper based questionnaire into the CAPI questionnaire by the IT and data processing team.

The lessons learnt during the pilot census were used by the NISR to improve and finalise the census questionnaires, containing 131 variables, as well as to revise the manuals of instructions for all the census functionaries.

The questionnaires used for data collection are presented in Annex of this report. Two different types of questionnaires were administered: one for private households and one for institutional households. The questionnaire for private households contained a person record, a household record and a mortality record. The questionnaire for institutional households contained only a person record with few questions.

4. Census publicity and sensitisation campaign

The success of the census is dependent upon the cooperation and participation of the entire populace. It therefore, becomes imperative to sensitize and educate the public on the importance of the census, an objective that was achieved through the implementation of the communication strategy developed for the census. A phased approach was assumed in implementing the communication strategy that includes awareness in different ways and dissemination mechanisms.

Some of the methods used for publicizing the 2022 RPHC are as below:

- a. Digital Communication Programme through websites, social media, and mobile platforms;
- b. Public Relations, events and mass communication;
- c. Traditional Advertising through mass and outdoor media;
- d. Community Mobilization (Umuganda).
- e. Radios/TVs shows communication on the census calling for the public participation.

Prior to census enumeration, a national publicity and sensitisation campaign was implemented in order to inform the public about the importance and relevance of the census (RPHC5), as well as to seek the active participation, involvement and collaboration of administrative authorities during the census enumeration.

A subtle and targeted publicity and awareness campaign was conducted before the census, which was later intensified and expanded to cover all districts and villages across.

NISR was responsible for organizing and coordinating, as well as preparing and implementing appropriate communication strategies to all

communities at both national and district levels. The materials were appropriately packaged and delivered to the districts for the implementation of communication activities. In addition, the NISR coordinated and implemented communication interventions as guided by the communication strategy, and where necessary, by the prevailing conditions at the district level. Census's tasks force at Province and District levels played an important role in the census public awareness.

The census results published including the population projections attest to the high level of cooperation of the political and administrative authorities and the effective participation of the general public in the entire census enumeration operation and processes.

5. Recruitment and training of field staff

The RPHC5 was conducted by personnel from various institutions: the NISR (the census executing agency), the Rwanda Defence Force through involvement of the Ministry of Defence, the Ministry of Emergency Management, the Rwanda National Police, the Rwanda Correctional Services and MINEDUC (Sector Inspectors of education and teachers).

The recruitment of Census functionaries was done by each institution according to the needs (i.e., number and categories of staff needed) of the NISR, except in the case of teachers whose recruitment was done by the NISR in collaboration with administrative authorities at the district and sector levels.

At each stage of census implementation, the necessary induction and mandatory training of NISR staff and census personnel took place. For example, the census mapping phase was preceded by the training of cartographers, while the pilot census and the actual census enumeration were preceded by the training of enumerators, data quality monitors and their supervisors.

About twelve weeks prior to the commencement of actual Census enumeration, cascaded trainings were organised for all categories of census functionaries, namely:

a. Core training for 59 people (exclusively NISR staff);

- b. Master training for 200 master trainers (NISR staff expanded to the Data quality monitors/team leaders and special institutions national coordinators);
- c. Training of trainers for 1,748 trainers organised in 30 training centres, one centre per district; and
- d. Training of 26,536 enumerators in 445 training centres spread across all sectors of the country.

The census training sessions focused on understanding of census questionnaire content, census enumeration processes and the correct completion of census questionnaires, reading and interpretation of census maps, practical role plays, and field practice. All the trainers and trainees were subjected to mandatory qualifying tests which they had to pass before being appointed.

In order to mitigate the risk of declining quality of training at the various cascading trainings, the training content was recorded in audio-visual materials from the studio. The recorded materials were projected in each training centre and were registered in each trainee's telephone for use in case of electricity outage or at home.

Regarding the organization of the training in each centre, four trainers were in charge of the training centre. The training in each of the centres were coordinated at the central level by NISR trainers who moderated all training sessions using CISCO Webex to ensure that all contents were covered and timely management of the sessions.

6. Actual census enumeration

As planned, the actual census enumeration of the population in private and institutional households was conducted across the country from 16th to 30th August 2022, immediately after the Census reference night (the night of 15th to 16th August, 2022). Although data-collection activities were carried out by well-trained enumerators, quality assurance of the Census enumeration was ensured through close supervision at various levels.

The census personnel deployed for the RPHC5 comprised the following personnel:

- a. Enumerators and support staff;
- b. Sector supervisors;

- c. Field monitors/data quality monitors and district team leaders;
- d. Field analysts, data analysts; and
- e. National coordinators.

In accordance with the instructions contained in the census manual, each personnel ensured the operations of daily census activities within their area of supervision. Enumerators were accountable for the work done on a daily basis to their sector supervisors, who monitored the progress using dashboards and field visits facilitated by two motorcycles hired to facilitate the transport of Sector Supervisors in their daily supervisory activities.

As the dashboard was accessible to all supervisors at different levels of supervision, each supervisor was expected to understand what was going on regarding the data collection and then provide explanations for any identified issues.

A team of 60 data monitors was working at NISR headquarters coordinated by 10 field analysts. They were responsible of the follow up on the progress of data collection through the dashboards in all enumeration areas. They interacted with sector supervisors on a daily basis by identifying the enumeration areas with low completion rates, and then suggesting possible solutions including redeployment of those who completed enumeration in EAs lagging behind. They were also reporting any issue that needed special attention of the coordination team.

The dashboards allowed coordination team to continually monitor the progress of census enumeration in all the 24,399 enumeration areas but also ensuring for quality of the census. The use of dashboards allowed the identification of the enumeration areas with risk of not completing the enumeration on time and where additional resources and support were needed (e.g. enumerators, means of transportation to ensure the completeness).

7. Post-enumeration activities

The post-enumeration activities include the Post-Enumeration Survey (PES), data processing, release of results, thematic analysis, and dissemination of census results. The use of technology at all stages of the census enabled the rapid and timely publication of the main indicators report, as well as the

tabulations and summary results contained in the thematic reports and other census products.

The PES was conducted from 16th to 30th September 2022, just in one month after the main census enumeration. The aim of the PES was to assess the census coverage/completeness and quality of the census data.

A total of 180 enumeration areas were sampled from all districts of the country. To assess census coverage, PES and census records were matched, a task that was carried out using data science techniques and the Python programming language. Matching is the process of checking whether records from two different data sets relate to the same household and/or person match or not. In this work, both automatic and clerical matching methods were used.

The census dataset –stabilisation, data-processing, and data-editing processes were completed within two months, after which census data tables for all thematic reports were generated. The final results were subjected to an in-depth analysis across 18 generic themes (one of which is presented in this report) in accordance with the analysis plan developed for each theme. Census monographs for each of the 30 districts will also be produced.

8. Data quality assessment

An independent quality review (available as an internal report to NISR) was conducted in parallel with the thematic analysis. This investigated the work done prior, during, and after the census enumeration to maximise the level of data quality. The assessment confirmed strong planning and quality assurance throughout the enumeration. Assessment of the key demographic and socio-economic variables also confirmed the good quality of the RPHC5 data in terms of representation of the population.

The overall conclusion of the assessment is that the RPHC5 was implemented with strong quality controls and gives an excellent representation of the population of Rwanda with generally good measurement of its structure, both in terms of spread and demographic and socio-economic characteristics. The high quality of the data with respect to coverage and representation is confirmed by the results of the Post-Enumeration Survey, which

measured the net coverage of the household population in the RPHC5 to be around 99% nationally with little variation across regions and by age and sex. Gross under-coverage was around 1.8% while gross over-coverage (erroneous inclusions) was around 0.2%.

The conclusion of excellent representation is also consistent with the plausible growth rate for the population over the intercensal period implied by the national results.

Some quality issues were identified on a few population characteristics. These include age heaping, particularly for ages with terminal digits 0 and 5. However, summary measures from Whipple's index, Myers' index and the UN joint score indicate

comparatively some improvement and a reduction in age heaping in the 2022 Census compared to the 2012 Census. There is also some evidence of under-reporting of infant deaths, and across other ages - hence the use of indirect methods is recommended for estimating mortality indicators.

In conclusion, there were no major quality issues identified in the 2022 Rwanda Population and Housing Census, except for some economic activity variables with low-quality reporting. The evaluation of key demographic and socio-economic variables as well as the triangulation of the data with other sources generally confirm the excellent quality of the RPHC5. Thus, the final database of the 2022 Rwanda Population and Housing Census is of high quality.

CHAPTER 2: INTRODUCTION AND OBJECTIVES OF THE ANALYSIS

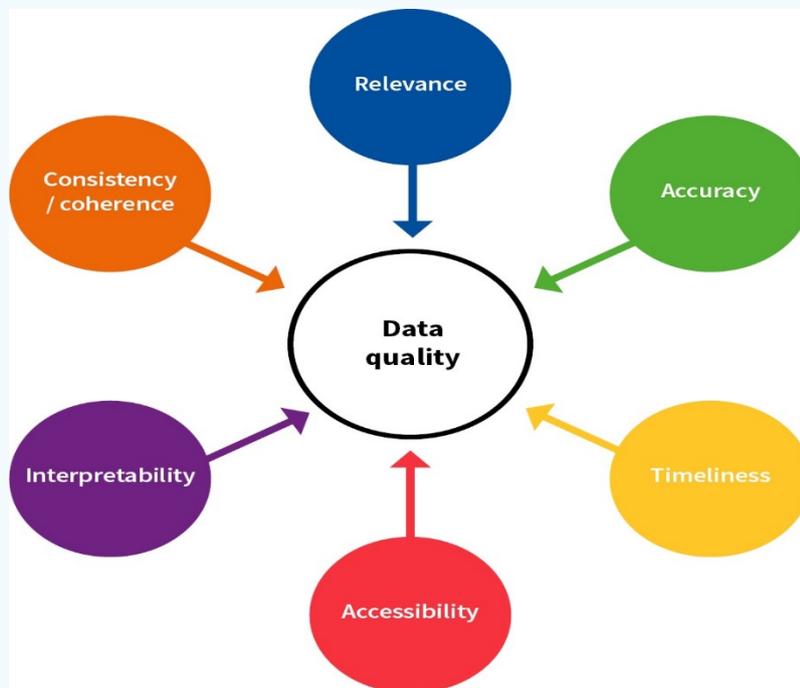

This report examines the quality of the Fifth Rwanda Population and Housing Census (RPHC5) conducted from 15th to 30th August 2022. The process involves a review of the processes and procedures for conducting the census, as well as the assessment of the coverage and contents of key variables in the census.

High-quality and reliable census data are important resource for social and economic planning. A country can make appropriate administrative planning if it has requisite and reliable information on different sectors of its economy. Hence, while the provision of timely census data is important, its quality assessment to ascertain data reliability is also very crucial. A thorough census quality assessment is a critical exercise that gives policymakers, programme implementers and other

users of census data the desired confidence and assurances that their planning, policies and programmes are based on accurate data.

United Nations Statistical Division has developed relevant handbooks, technical notes and manuals to support and promote the management of the quality of census and other statistical data (UNSD, 2022). These initiatives are essentially to provide technical and methodological frameworks to ensure the quality of official statistics across countries. As shown in Figure 2. 1, a vast body of evidence in several publications (Mahanti, R.,2019; Shazia Sadiq et al.,2013; Yong Zung,2015) identifies six dimensions of data quality, including relevance, accuracy, timeliness, accessibility, interpretability, and consistency or coherence

Figure 2. 1 Dimension of Data Quality

Source: Stats NZ (2017). 2018 Census data quality management strategy. Retrieved from www.stats.govt.nz.

In this report, quality assessment will focus particularly on the accuracy and coherence dimensions. Where necessary, the report made references to other dimensions of quality such as relevance, and accessibility. For example, relevance comes to fore in the design of census questionnaire. To ensure adequate assessment of accuracy, the life-cycle framework developed by Groves *et al* (2009) is adapted for a census situation. The census life cycle from quality perspective is presented in Figure 2. 2.

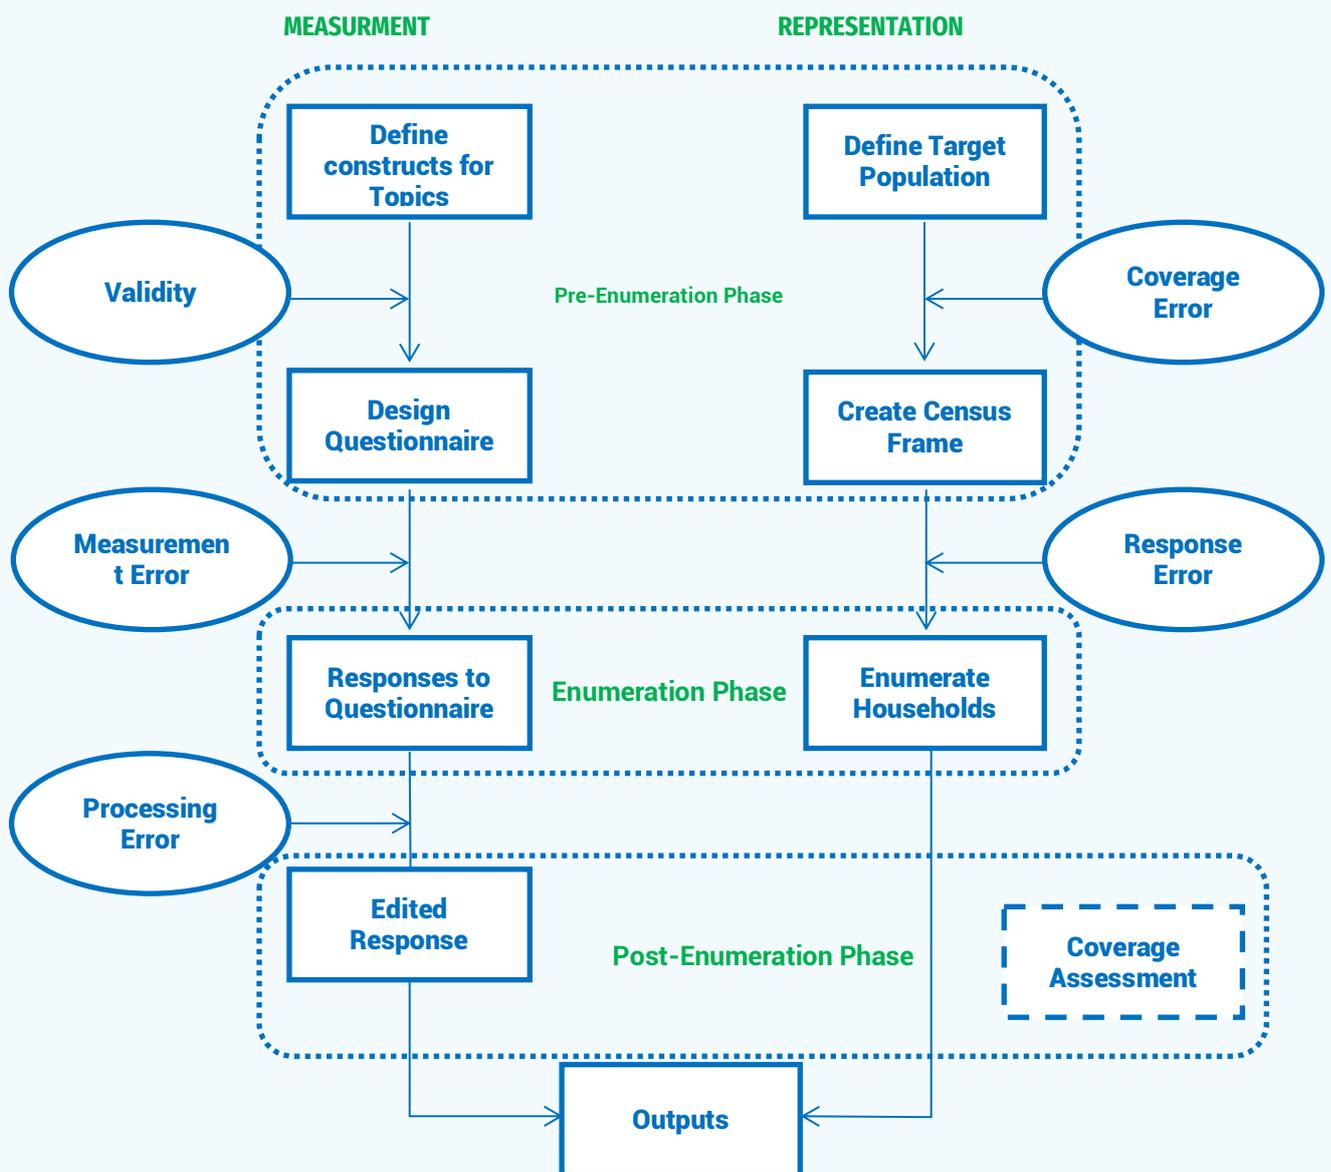

The life-cycle framework in Figure 2. 2 presents different operations and processes of producing final census results in two components: measurement and representation. Within measurement there are several steps (boxes) to the creation of an output and at each step errors (ovals) can occur. For example, a well-designed questionnaire may well give valid measurement of the underlying construct but if poorly administered there will be measurement error as the

resulting response is the true response with error. Within representation segment, there are also several steps and again errors can occur at each step. For example, there may be a perfect listing of all housing units (census frame) but if the enumerator fails to get responses from all units there will be response error. With the Census, coverage assessment is a step that takes place to assess the representation in the census.

The steps in Figure 2. 2 have also been split into three phases to cover the implementation of the RPHC5. These include a pre-enumeration phase, an enumeration phase, and a post-enumeration phase. In

the subsequent sections and chapters of this report, the three phases are presented where both measurement and representation of the census are assessed for possible errors. Chapter 3 of this report presents the assessment of pre-enumeration phase while Chapter 4 examines the enumeration phase. Chapter 5 and 6 present the assessment of post phase and evaluation of representation, respectively. Chapter 7 of the report presents the evaluation of measurement and representation with a focus on some key variables, including age, sex, fertility, mortality, and migration while Chapter 8 presents the conclusions and lessons for the future censuses

Figure 2. 2 : Census life cycle from a quality perspective

Source: adapted from Figure 2.5, p. 48, Groves et al (2009).

CHAPTER 3: PRE-ENUMERATION PHASE

The pre-enumeration or preparatory stage of a census is an important phase of the census enumeration. A careful planning and painstaking implementation of all the pre-enumeration activities is very critical to the successful conduct of a census and the quality of the census database. The pre-phase activities have significant impact on the overall quality of the final outputs. Hence, a vital part of the census quality assessment is the evaluation of different activities implemented during the pre-enumeration phase of the census.

Detailed planning for the RPHC5 Project started back in 2018 with the elaboration of the census project document detailing the plan, activities and indicative budget of the 2022 RPHC. Lessons learnt from the previous censuses conducted in 2002 and 2012 were very useful in planning for the 2022 census. The census team at NISR was able to build on the success of the previous censuses but also with the goal to improve timeliness of data release and therefore enhance its relevance for the use of policy-makers through timely release of the census results.

The United Nations recommends the use of technologies in census undertaking. This was reiterated in the United Nations Regional Workshop on the 2020 World Programme on Population and Housing Censuses held on May 29th to June 1st 2017 in Dar-es-Salaam, Tanzania. Rwanda was represented at the workshop by the Director of Census and the Director of ICT from NISR. The National Institute adopted the use of technologies in the 2022 RPHC in replacement of paper-based

questionnaires and other manual processes. From 2017, NISR started testing different processes and aspects of the census operations, including the technology readiness (network coverage, data transmission, programming, census questionnaire on smartphone, and data archiving). To ensure a smooth and effective deployment of technologies in all aspects of the census operations, a national census ICT committee led by the Rwanda Information Society Authority (RISA) was established under the auspices of the Ministry of finance and Economic planning. Hence, NISR procured 30,000 smartphones locally from Maraphones Ltd-Rwanda and a number of tests were performed to ensure that the brands are compatible and relevant for use in census enumeration.

The early commencement of planning for the census in 2018 was a conscious decision by the NISR to put the delivery of a high quality¹ output database at the centre of the RPHC5 Project. By June 2020, the project document, detailed activities and a clear road map of the 2022 RPHC were already available, and the process of fund mobilization had begun.

This chapter presents detailed information on the creation and testing of the questionnaire to assess the validity of the measurement of the desired² constructs. In addition, the chapter presents information on the representation stages up to the listing of housing units prior to the enumeration phase. The recruitment and training of enumerators is also covered in this chapter.

3.1 Development and testing of the questionnaire (validity and error measurement)

The development of census questionnaire for RPHC5 started with the first stage, which involved reviewing and building on the 2012 census questionnaire through engagement with relevant Ministries and other Government agencies to assess the relevance of the themes included in the questionnaire and also to identify possible gaps. After reaching a consensus on the themes or topics in the questionnaire, the design and layout of the 2012 questionnaire was the starting point for developing the questionnaires for 2022 Census.

As a default, most of the questions in 2012 census questionnaire were kept the same in 2022 census questionnaire. This not only increases the comparability of the data across time but made sense given the 2012 questionnaire was based on UN recommendations for census questions and content. However, there were some changes to the content such as New information collected on livestock type and agricultural activities (livestock type, type of crops and fruit trees) and ownership of mobile phones by the resident population.

¹High quality refer to the relevance, the accuracy, the timeliness, the punctuality, the accessibility, the clarity, comparability and the coherence

² It is important that the constructs should be relevant to the policy-makers.

In the area of disability, there was the positive move towards utilising questions from the Washington Group Questions on Disabilities that were consistent with the International Classification of Functioning. Additional information was also collected such as those relating to the official identification documents of the resident population. Further, there was a substantial change on all questions relating to employment and this was done in line with the new framework to capture the economic characteristics of the population.

After the inclusion of additional questions and the design and layout of the 2022 Census questionnaire, the questionnaire was pre-loaded on the electronic devices for use in the Computer Assisted Personal Interview (CAPI). Prior to the actual census enumeration, the

questionnaire was first reviewed by experts within the NISR. This was followed by a small-scale field-testing of the instrument to pilot the use of the questionnaire and the flow of the questions and controls. The testing of the questionnaire led to further refinement of enumerator instructions manual where it was discovered that enumerator–respondent interaction was potentially introducing measurement error with respect to the desired measurement. The result of the testing was used to further revise the questionnaire which was used in the pilot census. Through the pilot census, the general use of the questionnaire by enumerators through CAPI, flow of questions, as well as understanding and acceptability by respondents were then assessed on a larger scale

3.2. Creation and mapping of the enumeration areas (coverage errors)

Census is the most comprehensive source of demographic and socio-economic data at the smallest geographic level or administrative unit of a country. Therefore, a census must plan to maximise the coverage of the population. In the case of the 2022 Population and Housing Census, the process of maximisation started with the defining and mapping of enumeration areas (EAs). This was done both in terms of usual residents and via the inclusion of visitors in the enumeration of each household persons present.

There are different ways of measuring the success of a census enumeration, and the most important one is the census coverage. Prior to the main census enumeration, a census mapping was conducted from 18 October 2020 to 15 July 2021 to create a base map to be used for the whole process of census operation. The mapping was essential for planning and creating small manageable units – referred to as enumeration areas (EAs). The mapping was also done for other important purposes, including updating the existing administrative boundaries of the country, creating a georeferenced database of housing and household location that are linkable to the census results, creating a georeferenced database of basic social and economic infrastructures, and providing support structure for the monitoring of census enumeration through the use of GPS technology, dashboard and interactive maps.

The census mapping was done first to ensure that the total land area of the country is divided into non-overlapping enumeration areas which were assigned to enumerators. To create enumeration areas, data with

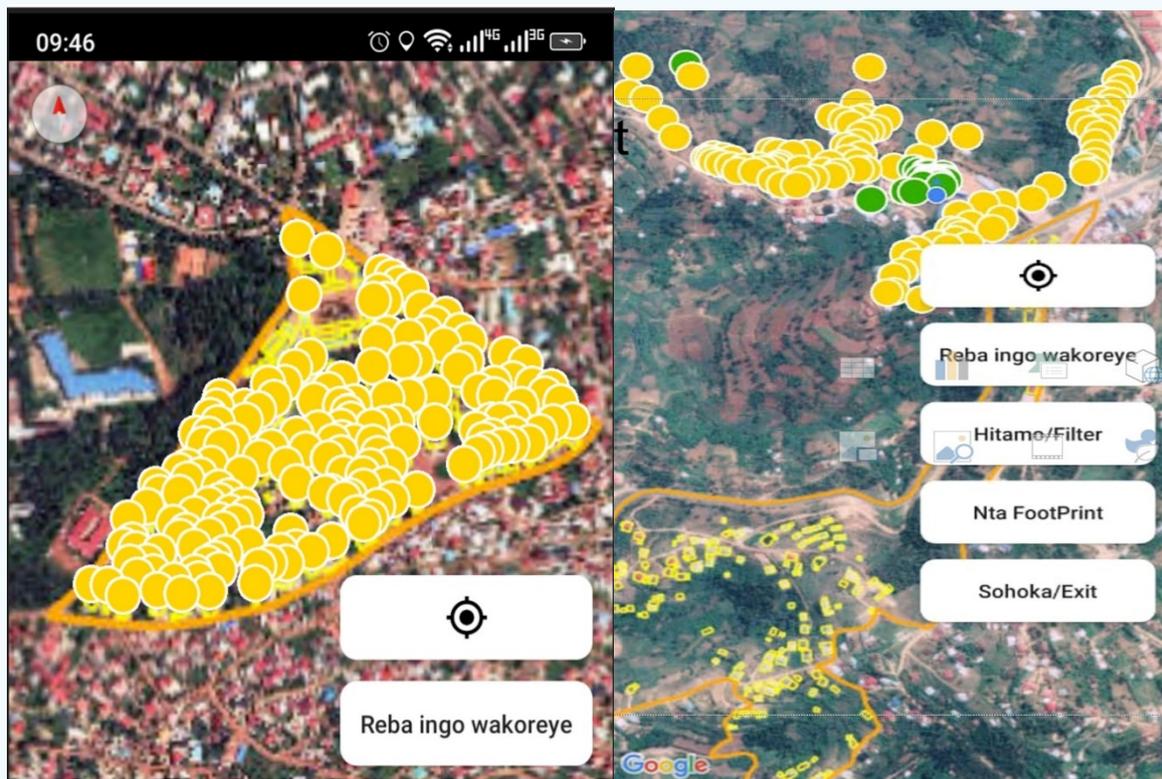

location and shape of buildings (building footprints) as well as high resolution satellite images were utilised. While in the field, every single building was tagged with information about the use of each building and details on the number of households in case of residential buildings. The lowest level of deployment during the field work was a village. After the village was completed, a total number and location (by GPS coordinates) could be available.

In the office, the boundaries of enumeration areas were created by staff on high resolution satellite images, a semi-automated process considering existing administrative boundary of villages, number of households with an average of 130 households at cell level. Even though the EAs boundary were created from the lowest administrative unit which is a village, the decision of considering the average of household at cell level was motivated by the fact that it is possible to organise support inside the cell without requiring a lot of logistics means. Sticking to a certain threshold of a number of households for each EA could have led to the creation of many and not optimised EA than considering a certain average at a slightly higher administrative unit which is a cell. The average of 130 households was chosen based on the early testing of the questionnaire during the pilot census. The pilot census showed that choice of 130 households is a reasonable decision considering the amount of time it will take to enumerate one household and the total period of fifteen days allocated to the census data collection.

The first phase of census mapping was about data collection from field (18th October 2020 to 15th July 2021). The second phase was about data processing and EAs boundary creation (July 2021-January 2022), then automated maps production took place in February 2022. The maps were produced in digital format loaded on smartphones and consumed directly with the census data collection application and used for the provisioning of devices used for the data collection (assigning each device to a specific EA).

Enumeration Area maps were provided for enumerators in digital format. The map included different layers, an image showing the boundary of enumeration area as well as reference buildings (from census mapping in yellow) (Figure 3.1). The reference buildings were used for reference location for data collection but also enumerators could add missing buildings. Internal controls were set to crosscheck the location of enumerators with the reference buildings and error message could pop up in the app in case of mistakes. As the enumeration continued, the enumerated buildings would turn green on the map..

Figure 3. 1 Enumeration Area map in Cs Entry app

Source: Fifth Rwanda Population and Housing Census, 2022(NISR)

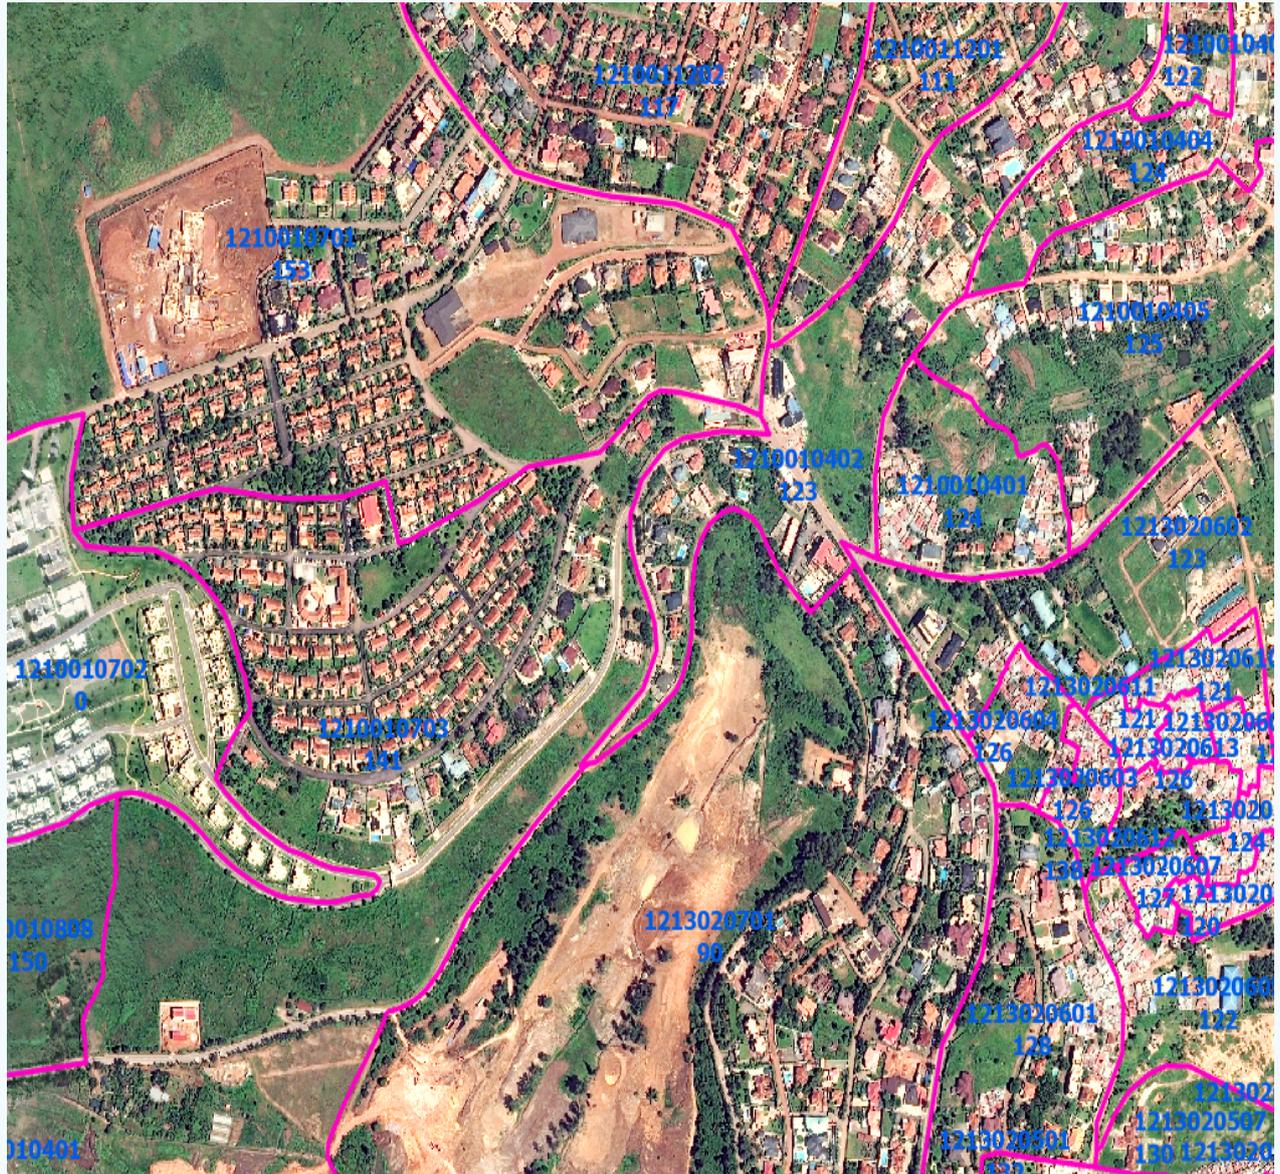

Generally, the use of technology greatly contributed to the successful implementation of different phases of the 2022 Rwanda Population and Housing Census. Overall, such steps including the deployment of technological devices for creating and mapping the enumeration area, as well as for fieldwork management using tools like location dashboard, progress dashboard, and key statistics dashboards, amongst others.

3.2.1 CENSUS MAPPING – DELINEATION OF EAS

Technological devices deployed in the census mapping included the satellite image which was used to capture base map and building footprint, ArcGis software – used for field mapping, and DBM (Microsoft SQL server) – used for data management. In total, 24,347 small and manageable geographic units (Enumeration Areas) were delineated. As shown in Figure 3.2, EAs were almost homogenous with similar geographic conditions and almost similar number of around 130

households in each EA.). The EAs also have clear boundaries and similar workload for enumeration. Over 4 million building footprints were counted during the 2022 PHC mapping.

Figure 3. 2 Delineation of Enumeration Areas

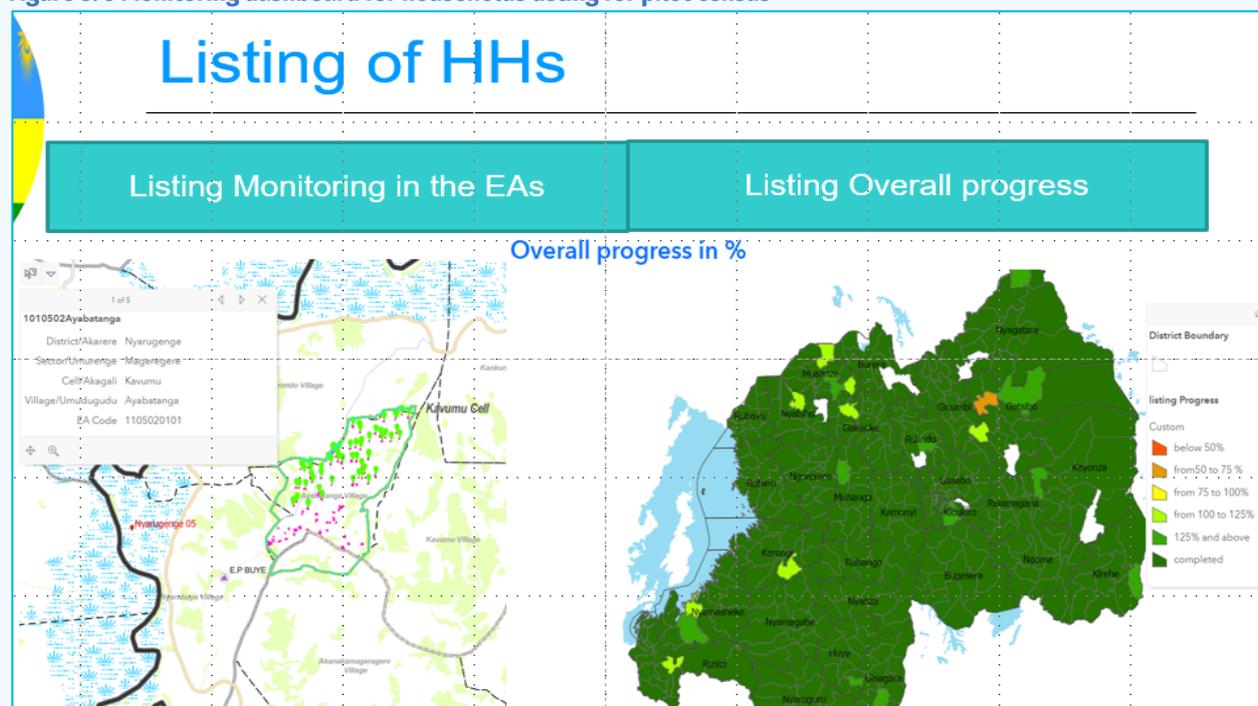

Source: Fifth Rwanda Population and Housing Census, 2022 (NISR)

3.3 Pilot census

After the census mapping, the next activity implemented was the pilot census. The pilot started with the household listings which took place on September 11th-15th, 2021. Listing of all the private households was done in all the sampled 600 EAs across the country. Also listed were institutional households, including 2 refugees' camps, 2 correctional centres (prisons), 5 military barracks, and 2 police stations just to mimic what will be done in the real census. Figure 3.3 presents the dashboard used for monitoring the progress of households listing across the country.

Figure 3.3 Monitoring dashboard for households listing for pilot census

Source: Fifth Rwanda Population and Housing Census, 2022,(NISR)

3.3.1. PILOT CENSUS ENUMERATION

After the listing of households for the pilot census, the enumeration for the pilot was conducted in a total of 65,586 occupied households from 16th to 30th September 2021. The pilot census was meant to be conducted exactly one year before the planned census so as to conform to the exact period of the main census. Hence, the pilot census took place in September 2021 – exactly 12 months before the actual census enumeration to ensure that the field conditions are identical. Unfortunately, the pilot was disrupted by Covid-19 pandemic as the country was in lock-down during the period.

The pilot census is a comprehensive process that involves testing of all census procedures such as the adequacy of the census plan and of the census organization. The pilot mainly tests the operational feasibility of conducting the main census rather than make population estimates. Pilot census was also conducted to test the equipment, recruitment process and field materials such as smart phones. In the context of using hand-held devices, testing included daily data transmission, network connection, battery life of the device, and field monitoring using dashboards. It was critically important to undertake a set of tests of technologies related to the fieldwork, data capture, transmission, processing, analysis, and the efficiency of

editing and tabulation applications. It was also useful for evaluating different field techniques to increase response and participation.

The Pilot Census took place in 600 EAs randomly selected from across Rwanda. The Pilot undertook a comprehensive and large-scale test of the processes and activities in the pre- and enumeration phases ‘on-the-ground’, thus covering several aspects of the census enumeration, including recruitment and training of enumerators, EA and house listing, use of the questionnaire, as well as responses to the census questions. Hence, one of the objectives of the Census Pilot was to ensure that measurement errors are minimised in the actual census data collection. The pilot census was also undertaken to test the use of technological devices in data collection with a view to address any technical glitches that may arise and other challenges that may affect the smooth conduct of the census. During the pilot census, the skipping pattern of the question was also tested and necessary changes were made thereafter. Fieldwork management was also tested during the Pilot Census to put necessary measures in place to ensure effective management of field operation and also to minimize response errors. Data from the Pilot Census was also analysed to address any issues with respect to response and measurement

errors prior to the actual census enumeration. Analysis of the pilot census was done to (i) assess if the questions were well understood by the respondents and to confirm the appropriateness of their responses, (ii) determine if skips worked well as intended, and (iii) assess if the CAPI applications function well. Findings from the pilot census were used to facilitate a more desirable allocation of available census resources. Also, the pilot data provided understanding on respondents' interpretation and reaction to census questions and instructions, and this was used to revise the questionnaires for better and clearer understanding.

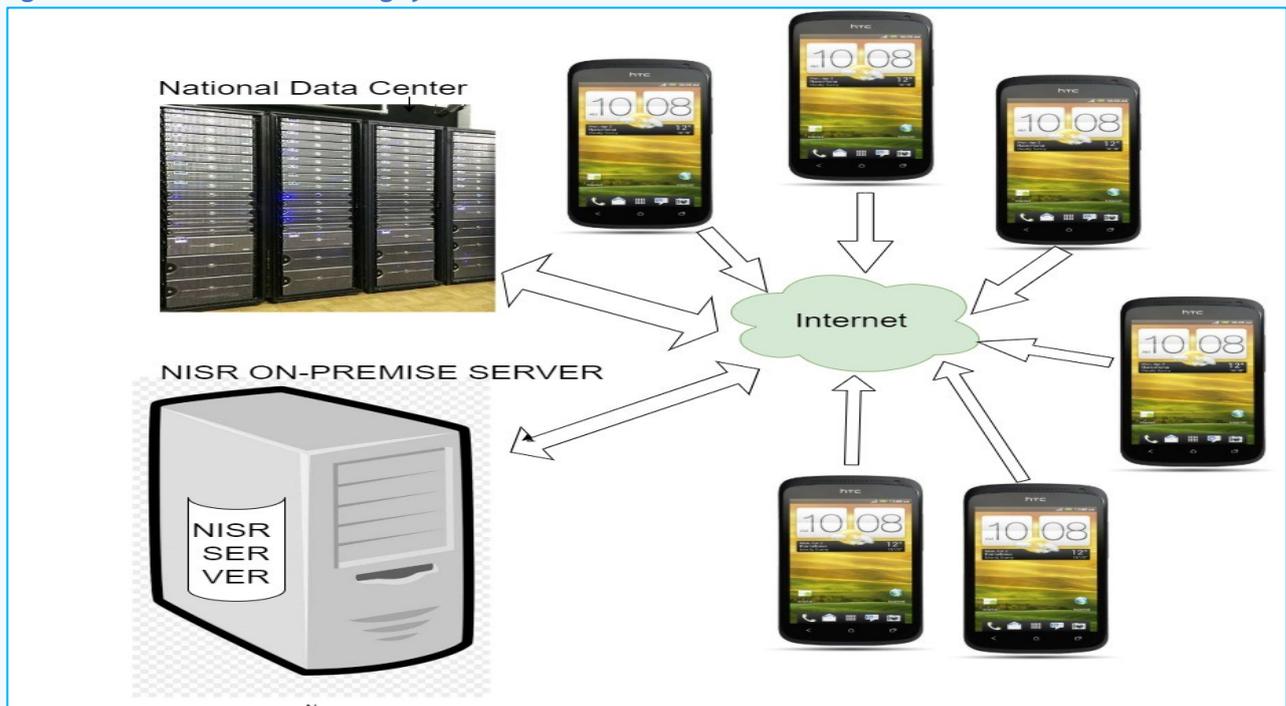

With respect to response error, several lessons were learnt. First it was clear that more flexible hours would be required for the enumeration phase, especially in urban areas. A call-back card was added to allow the household members to call the enumerator to arrange a suitable time for enumeration. Second, the size of the EA

had been based on the mapping exercise and in some cases, this had seriously under-estimated the number of dwellings. This was especially the case in the City of Kigali where there has been rapid population growth due to the rural-urban migration. In some cases, EA boundaries were revisited, and the team split the EAs that were too large into more than one EA and assigned support staff to complete the enumeration. More enumerators were assigned from the list of additional ones to boost the enumeration capacity. To ensure a smooth process, a live management information system was put in place to first track the listing of each EA and then to track the progress of enumeration. The RPHC5 was CAPI-based and it benefitted from technological innovation with the use of a number of IT-based monitoring tools (dashboard, Mobile Device Management) for a rapid and better monitoring of field activities.

3.3.2. DATA TRANSMISSION AND HOSTING REPORT FOR THE PILOT CENSUS

The data collection during pilot census was done using CsPro application. The application was developed in such a way that allowed transmission of data to the central server (Figure 3.4 and Figure 3.5) immediately after completing household enumeration. This made a positive impact on the overall quality of the pilot census data as it enabled the supervisors and the management team at the NISR to get data in real time for proper monitoring of the data collection exercise. Figure 3.6 shows the dashboard used for monitoring data collection during the pilot census.

Figure 3.4 Transmission and Hosting System

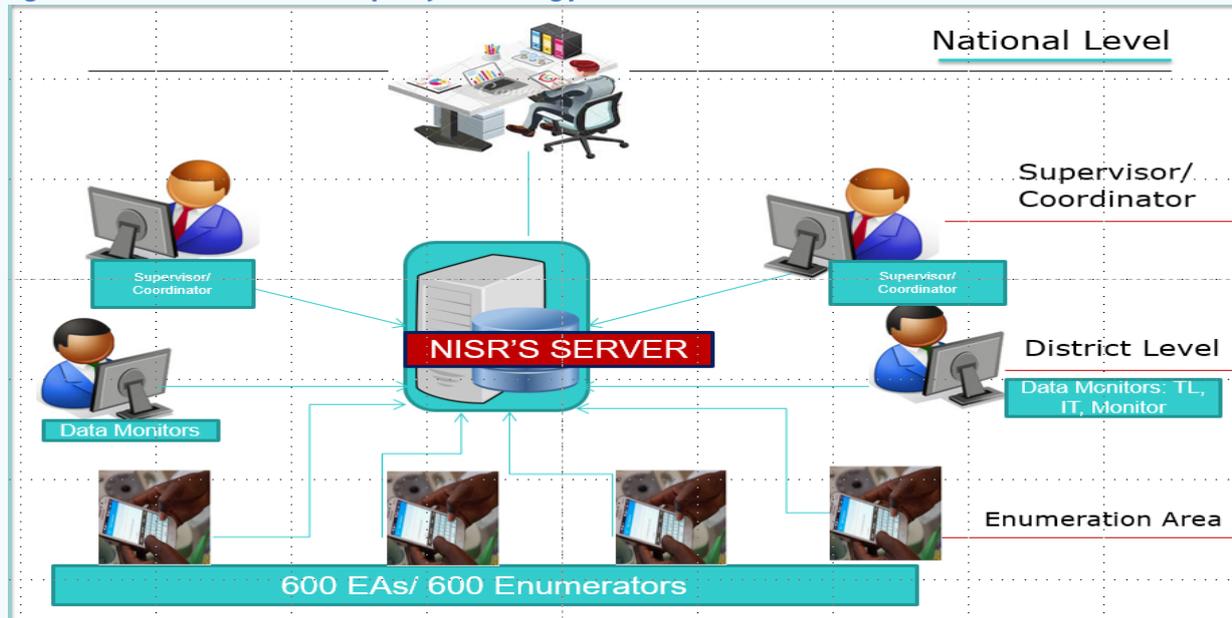

Source: Fifth Rwanda Population and Housing Census, 2022(NISR)

3.3.3. FIELD MONITORING FOR DATA QUALITY

Dashboards were used for monitoring data collection during pilot census in order to manage the information/data, as well as track, analyse, and display key performance indicators, metrics, and data points real time as data collection progressed. Dashboards were also used to assess key variables such as age, sex, fertility and mortality.

Through this process, supervisors and the NISR team were able to track the quality of data being collected real time (Figure 3.7). Also, dashboards were used for field management to track enumerators' daily performance, cumulative progress and assessment of the completeness of the census enumeration at different levels from national to EA level.

Figure 3.7 Pilot Census field data quality monitoring process

Source: Fifth Rwanda Population and Housing Census, 2022(NISR)

Several lessons were learnt from the pilot census with respect to the general organisation and management of the enumeration phase. Lessons learnt from the pilot census contributed to the appropriate planning of different aspects of the census operations, including the questionnaire design, deployment of CAPI application and controls, tabulation and analysis plans, EAs boundaries delineation, internet connectivity and data transmission, recruitment and training of enumerators, as well as communication campaign and field

deployment. The pilot census also allowed for development of the listing and enumeration to help minimise coverage and response errors. Lessons from the analysed pilot data were used to revise the census questionnaire. As a last phase, the final questionnaire was reviewed by the Census Technical Committee. Notwithstanding the analysis done on the pilot census, some quality issues were identified in the responses to the questions on economic activity. Details on the issues identified are provided in Chapter 7 of this report.

3.4 Enumerator's training (measurement errors; coverage errors; response errors)

In preparation for the actual enumeration for the 2022 Rwanda Population and Housing Census, 26,987 enumerators and 2,148 reserve staff were recruited for training and deployment for the enumeration within private Households, while 308 enumerators were appointed to do enumeration within institutional

households. One enumerator was deployed to cover an EA during the census enumeration. In addition, one reserve enumerator per cell was recruited to serve as backup and cover for issues such as illness or unavailability of some enumerators or to provide support during enumeration in one of the neighbouring

EAs. The reserve enumerators covered the excess households in EAs with more than the target maximum of 130 households. Local primary teachers and youth were recruited as enumerators. This was to ensure that enumerators would have sufficient level of education needed to understand the nitty gritty of census enumeration taught during the training and also to ensure that enumerators have sufficient capacity to properly use smart phones for data collection. Besides, primary school teachers were recruited to serve in their locality to ensure commitment to their various local areas and reduce commuting time between EAs and their homes. Other important considerations for engaging local teachers include having knowledge of local areas which is needed in house listing and being a respected member of the local village to aid cooperation during the enumeration.

Detailed training materials in form of audios and videos were prepared covering the use of Cs entry application for the identification of an EA's boundary (*coverage error*), the listing of households within the EA (*coverage error*), and then the enumeration of the households both in terms of getting a response with the identification of all individuals to be enumerated (*response error*), as well as the correct completion of the questionnaire for the identified individuals (*measurement error*). The training leveraged the use of technologies by developing

, the cascading trainings were organized at different levels starting with core training organized generally for the NISR technical staff involved in the technical implementation of the census. In the master training, the core team was expanded to include special institutions, special team and contractual staff who later served as team leaders and office data quality monitors.

pre-recorded materials. The materials included audios and videos of examples of interviews demonstrating how an enumeration should be done in different scenarios.

To ensure proper training of the enumerators, the hierarchical structure of census management was used to cascade the standardised training from the national level down to the local level. The first two levels of training (core, and master training) were face-to-face sessions while the last two were hybrid (online and face to face) trainings. The virtual trainings were facilitated using the Webex application. The core training was held from the 9th to the 13th May 2022, then followed by the training of master trainers which took place from the 15th to the 28th May 2022. The training of trainers was done in two phases from the 4th June to the 10th July 2022, and it was done during weekends because some trainers were teachers and sector inspectors of education who were busy with their teaching responsibilities in their schools and sectors during the weekdays. The training of enumerators was done between July 21st and August 9th, 2022. The training was done very close to the listing, and enumeration period purposely to ensure that enumerators do not forget what they learnt during the training.

As shown in

The training of trainers involved the sector data quality monitors who were meant to facilitate the main training and supervision at sector level. Activities in the training sessions include practical exercises, mock interviews, field data collection and data transmission, and testing of all aspects of the training.

Table 3. 1 Cascading trainings and numbers of participants

| Training name | Date | Number of participants |
|---------------------------------|------------------|------------------------|
| Core training (NISR Staff only) | 09/5 – 14/5/2022 | 59 |
| Master training | 15/5 – 28/5/2022 | 200 |
| Training of trainers (Phase1) | 04/6 – 10/7/2022 | 1,748 |
| Training of trainers (Phase 2) | 04/7 – 08/7/2022 | 445 |
| Training of enumerators | 21/7 – 09/8/2022 | 26,536 |
| Refresher training PES | 04/9 – 09/9/2022 | 210 |

Source: Fifth Rwanda Population and Housing Census, 2022(NISR)

3.5 Creation of the enumeration lists within each EA (coverage errors)

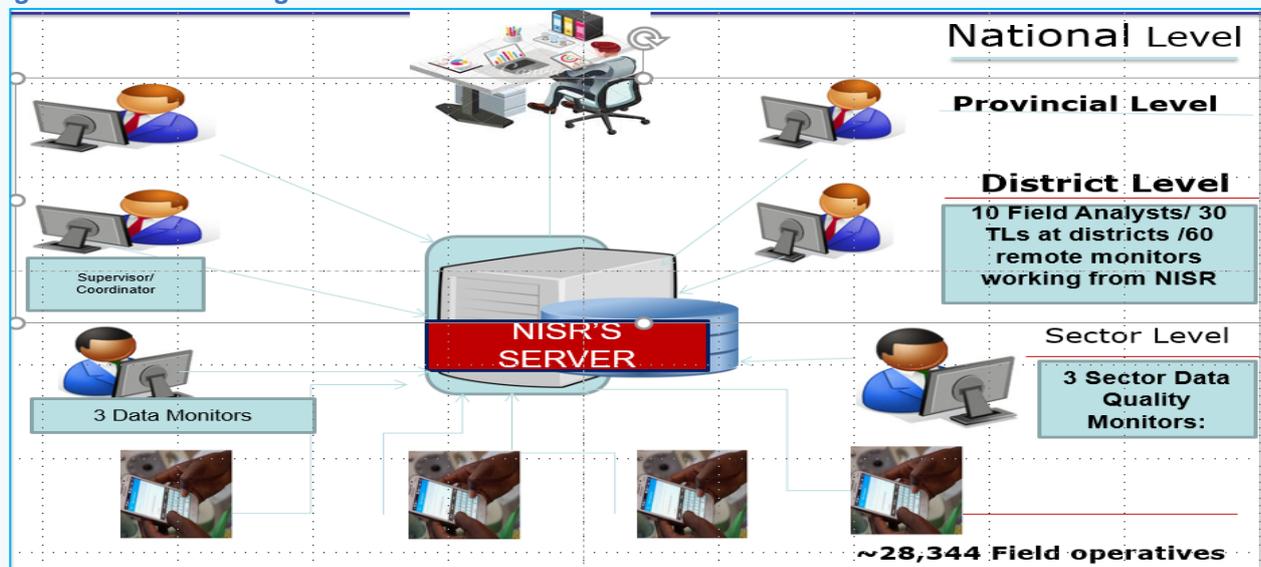

Census is the most comprehensive demographic data source and therefore must have a total coverage of all the persons resident in the country. To ensure 100% coverage, an important step in census planning is the identification and listing of all housing units within all EAs across the country. A suitable timing was chosen (10th to 14th of August, 2022) for the identification and listing of housing units for the RPHC5. The dates were carefully chosen to ensure sufficient time for planning and listing of all housing units and to ensure that this all-important exercise takes place close to the actual census enumeration as much as possible. To ensure easy movement, motorcycles were provided for the sector data quality monitors (Sector education Inspectors, and selected youths or teachers) who were in charge of monitoring fieldwork at sector level.

The first stage of the house listing was the identification ‘on the ground’ of each EA boundary. Prior to the listing, enumerators were trained³ on how to use the map uploaded in Cs entry application to identify an EA’s boundary on the ground. The identification by each enumerator was done in consultation with sector data quality monitor and the enumerators assigned to the neighbouring EAs and the relevant Village Heads. This process ensured that all housing units close to a boundary were assigned to just *one* EA before the listing took place.

The second stage involved actual listing of housing units which took place over a period of 5 days between 10th and 14th of August, 2022. The exercise was closely supervised by the sector supervisors via the dashboard to ascertain the quality and progress of work done each day. The result of the house listing was of a high quality⁴ in all EAs as full coverage was achieved within the planned time-frame with the feedback reported back to the central NISR census team. Report from the post-enumeration survey presented in Chapter 5 confirmed the high quality of the house listing exercise for the RPHC5.

As it was done during the pilot census, data from listing of housing units for the census were sent directly to the server. This aided a robust monitoring of fieldwork at all levels – the national (using coordination team, field analysts, office data quality monitors, and data analysts), district (using district team leaders and district data quality monitors), and sector levels (using three sector data quality monitors per sector). Sector data quality monitors comprised one Sector Inspector of Education and two monitors drawn from among the Youth. There were also representations from the army, police, and correctional services. Figure 3.8 and Figure 3.9 present the field monitoring and field interaction mechanism dashboards used in the 2022 PHC.

Figure 3.8 Field monitoring dashboard

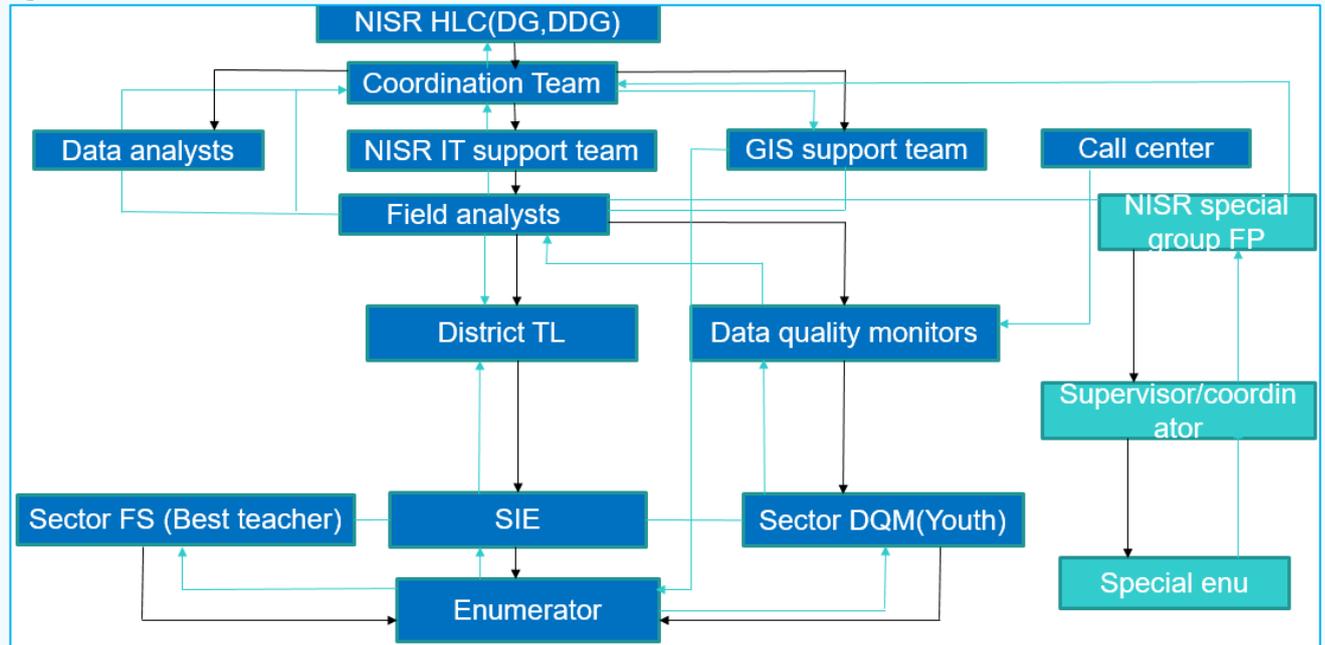

Source: Fifth Rwanda Population and Housing Census, 2022(NISR)

³ The delivery of enumerator training is covered in Section 2.4.
⁴ The final quality of the listing can be assessed using the Post-enumeration Survey but the planning, management, and

implementation of the listing was a success getting as close as possible to 100% coverage.

Figure 3. 9 2022 Census interaction mechanisms

Source: Fifth Rwanda Population and Housing Census, 2022(NISR)

3.6 Listing institutional households (coverage errors)

The vast majority of the Rwandan population reside in residential households. However, there are important sub-groups of the population that reside within institutional households and homes. These include army barracks, police barracks, prisons, and other institutional homes such as religious centres and hotels and refugees’ camps. These require special treatment in the census to ensure they are enumerated. At the District level, a list was created covering all army barracks, police barracks, correctional services and other institutional homes. The enumeration of these institutional households was then managed separately with their own National Coordinators (RDF, RCS, RNP,

and MINEMA in charge of refugees’ camps management). Other institutional households such as religious centres were identified by the standard enumerators as part of their listing and were recorded at the end of the listing to be enumerated by the standard enumerators during the enumeration phase. Another important sub-group not within residential households are the homeless. With the help of the Village Heads, the enumerators identified the locations of homeless individuals within their EAs during the listing stage to ensure they are enumerated as members of an ‘institutional household’ for that EA.

CHAPTER 4: ENUMERATION PHASE

After several months of careful and painstaking planning, the census enumeration for the Fifth Rwanda Population and Housing Census took place on the designated Census Night. The actual enumeration took place from 16th to 30th August 2022. The careful planning by the NISR ensured that necessary processes and logistics were put in place to ensure a smooth implementation of the census enumeration. Important parts of the preparation included the central reporting of final house listings to the NISR census team, and procurement of 30,000 smart phones and their configuration with relevant applications such as CS Entry application and Mobile Device Management application. The early purchase of the electronic devices was done prior to data collection to ensure sufficient time for their configuration and other necessary planning and steps required for a successful digital census. Other important measures put in place during the planning included the design of dashboards for management of field operation

and for monitoring daily progress as well as the quality of key statistics collected during enumeration.

Where EAs were larger than expected, as in a particular case in the City of Kigali additional resource from the pool of reserve enumerators and youth was made available to ensure that the enumeration phase could run smoothly and be completed during the enumeration period as planned. This was important as the testing had given an indication of the average time taken to enumerate a household, and therefore it was known that above a certain threshold of households it would not have been possible to complete the workload in thirteen days. Prior to the enumeration phase, the enumerators identified the EA boundaries and then did the households listing. Where necessary, additional staff were brought to cover the listed households in the large EAs. Needless to say, the use of CAPI contributed to a seamless enumeration phase of the census.

4.1 fieldwork management

The 2022 PHC was a digital census. By digital census, it means that the data collection was not done on paper questionnaire but through the use of electronic devices such as smartphones and tablets. The use of technology was not limited to data collection but also was extended to other aspects of the census, including the fieldwork management.

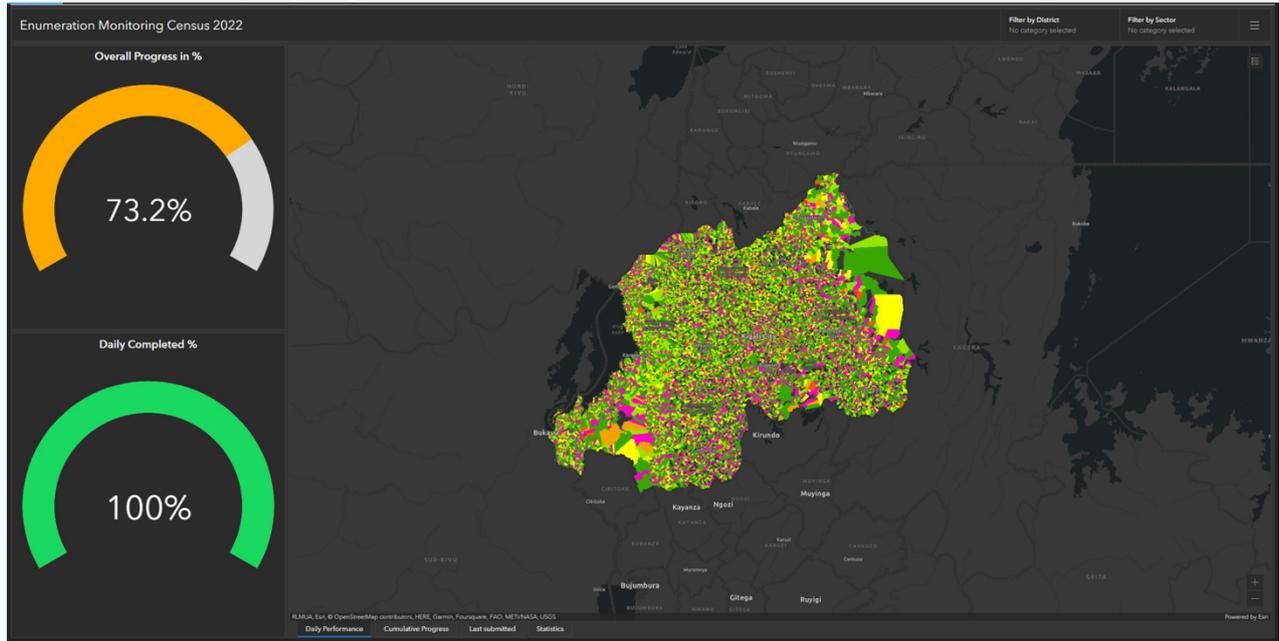

The fieldwork management was divided into two main pillars – the progress and the location. The progress means the work progresses in line with a certain target on live and on daily basis. The location pillar focused on coverage (i.e., the whole enumeration area buildings are covered) and the attendance (i.e., enumerators are collecting data in the right location and at the right time).

A fieldwork-monitoring dashboard was the main tool built to support different levels of fieldwork monitors. It

was accessed online by different level of users including the national coordinators, and district and sector data monitors. The monitoring dashboard was functioning based on data collection flow, where enumerators could automatically send the data once a case is completed.

On a daily basis, the data collection assumption was that every enumerator could achieve a target of 13 households per day. Different colour codes were designed to show the progress, from red which indicates a poor progress, to green, indicating good progress, while purple signifies a case of out of range. The field monitoring task was to focus on poor progress and abnormal cases. The map of daily progress (Figure 4.1) shows EA changing colours throughout the day as enumeration progressed.

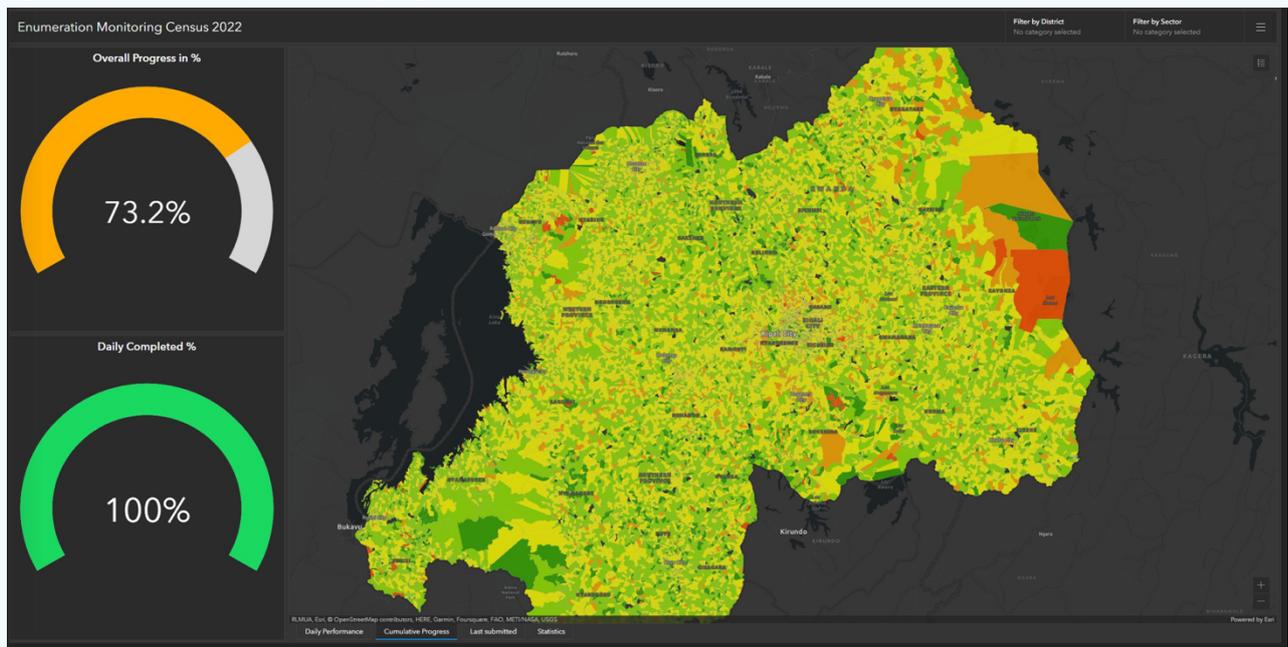

Figure 4. 1 Dashboard, Daily Progress

Source: Fifth Rwanda Population and Housing Census, 2022 (NISR)

The cumulative target was set based on the total number of households assigned in the EAs and the total number of days for the census data collection. The same colour codes (red to green) were assigned to monitor different levels of progress. As shown in Figure 4.2, the map of daily progress shows EA changing colours as data collection progressed each day.

Figure 4. 2 Dashboard, Cumulative progress

Source: Fifth Rwanda Population and Housing Census, 2022 (NISR)

Apart from monitoring progress, managers at higher levels could get summary about the progress made on data collection regarding key statistics like the number of completed EAs, as well as aggregates to different geographic units like province (Figure 4.3).

Figure 4. 3 Dashboard, Key statistics

Source: Fifth Rwanda Population and Housing Census, 2022 (NISR)

As part of data collection management, enumerators used reference buildings provided for them for data collection. They could also add on the maps missing building locations. In the background the data collection app could capture the real location of the enumerator. As indicated in Figure 4.4, real location compared with reference building could provide information about the place where the enumerator is collecting data from and computer programs to decide if it is a wrong or right location.

Figure 4. 4 Dashboard, locations

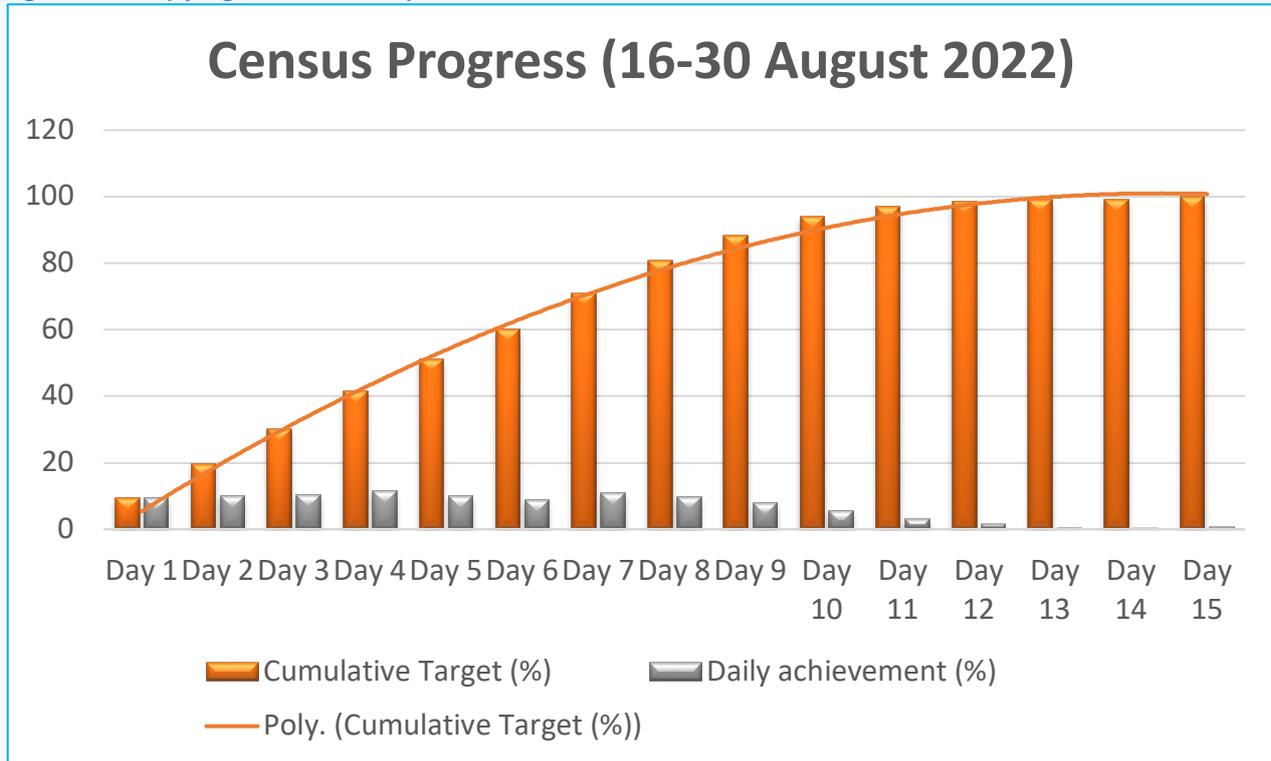

Source: Fifth Rwanda Population and Housing Census, 2022(NISR)

A key component of the fieldwork management was the daily feedback of number of individuals enumerated in each EA through the dashboard, so that progress with respect to response error as measured by the listing could be monitored at all levels. For each EA, expected progress in the dashboard was spread evenly across 13 days allowing for two days at the end to mop up where needed. Figure 4. 5 presents daily progress over the period of the census data collection (16th -30th

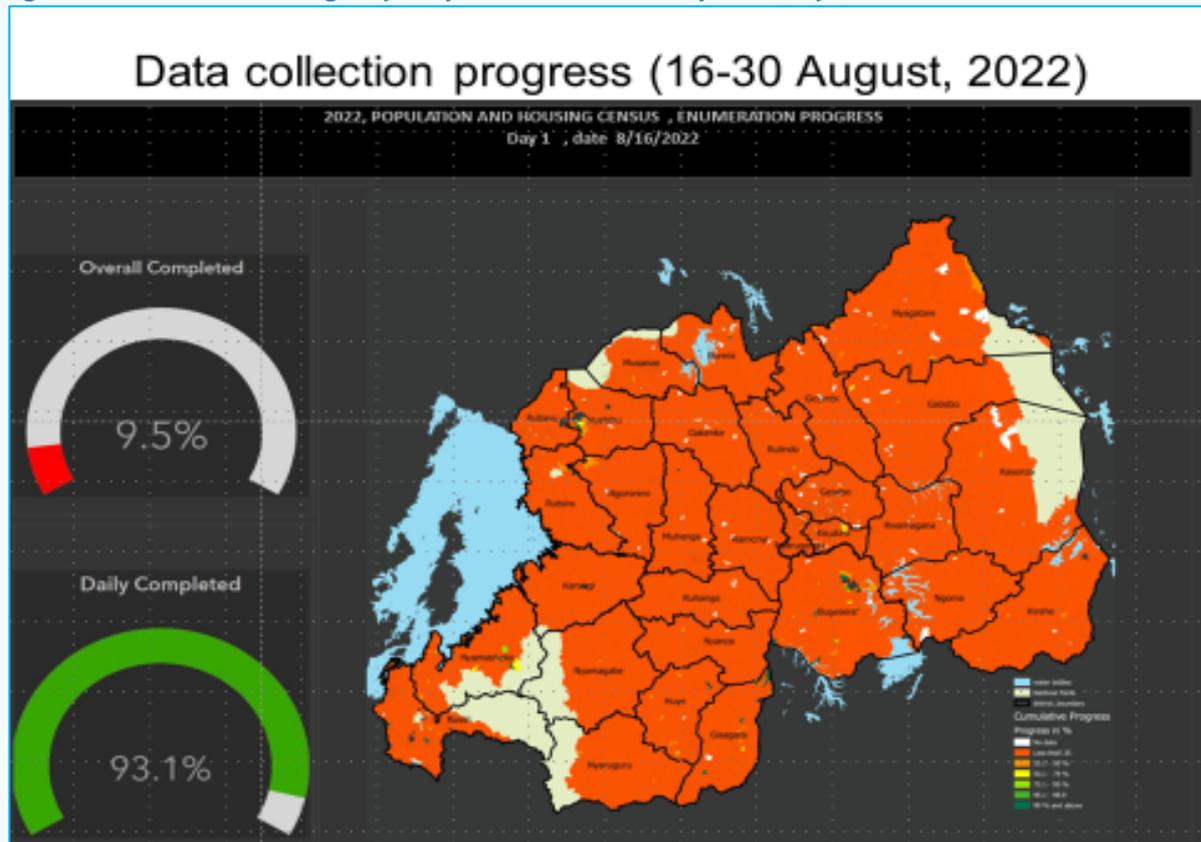

August 2022). By the end of this initial period, some additional resource was targeted at City of Kigali in a final push towards complete enumeration. As it was done in the pilot census, deployment of technologies facilitated the use of dashboards for monitoring the census completeness (Figure 4.6, Figure 4.7, Figure 4.8) coverage and quality of some key indicators.

4.2 Enumerating Institutional Households (Response Errors; Measurement Errors)

The questionnaire for institutional households was smaller and simpler than the main household questionnaire and did not include the employment section, the household section and the mortality section. It was administered on an individual-by-individual basis to the members of the institution. As already discussed, the large institutional households including correctional services and army barracks were

enumerated by staff recruited from the relevant organisations to aid cooperation ‘on the ground’. For hotels, these were dealt with by the standard enumerators towards the end of the enumeration phase; while the homeless individuals identified within an EA during the listing phase were dealt with at the very start to ensure those actually present in the EA on Census Night were enumerated.

CHAPTER 5 : POST ENUMERATION PHASE

With the details of assessment done on the pre-enumeration and enumeration phases of the 2022 Rwanda Population and Housing Census presented in Chapters 2 and 3, this chapter presents information on the assessment done on the post enumeration phase of the census. Evidence outlined in Chapters 2 and 3 points to a well-planned, well-managed and well-implemented enumeration phase that maximised the coverage of the RPHC5. More importantly, using CAPI application on the smart phones greatly improved data quality by eliminating potential weak point and errors associated with data entry in the pen-and-paper personal interview (PAPI) as was done in the 2002 and 2012 censuses. In addition, the use of restriction and skip patterns in the electronic devices contributed to minimise measurement and response errors.

The post-enumeration phase of the 2022 census includes data cleaning, data editing and imputation for non-responses. Also, other tasks implemented in the post-enumeration phase are data analysis and tabulation, assessment of data quality and thematic reports writing for the use of policymakers, government ministries, development partners and non-governmental organizations. Given that the use of electronic devices eliminated some stages of census enumeration, including storing of paper forms, data coding and data entry, this chapter presents assessment done on data editing and imputation for the non-response cases.

5.1 Data Editing And Imputation For Item Non-Response

The use of the Computer Assisted Personal Interview (CAPI) has significantly reduced the number of internal inconsistencies that are usually found in the census data. Notwithstanding, as a standard practice in a census enumeration, it is necessary to apply edit rules to identify possible internal inconsistencies in the data, and then to make a minimum change to the data so that a record can pass the edit rules. To guide against errors and to reduce the enumerators' work and avoid a lot of

back and forth during the interviews using CAPI, the census data collection application was designed with limited internal consistency checks. The census team also designed the error detection and editing specification rules as presented below:

5.2 Error Detection Rules

The error detection program was looking for three types of issues:

- 1) Some complex checks that required checking several variables were intentionally left during the data collection. These checks also include internal consistency checks;
- 2) Some issues that the field supervision teams identified and documented; and
- 3) Checking of the universe of each variable to identify a wrong skip or data entry error.

5.3 Editing Specification Rules

The subject matters specialist of each topic provided an editing specification. When the error was detected, there was a rule to fix the issue. Generally, the rule of correction consists of making a minimal change to the data so that a record can pass the edit rules. For example, if the census data has record of a 24-year-old man, married to the male head-of-household aged 28, and with a report of full current fertility history, such record lacks internal consistent. The minimum rule is to change the gender of such individual to female. In this case the edit rules that only females ages 15 to 49 that

can have children and only a female of marriageable age can get married to a male not only highlight the inconsistency but define the imputation required to correct the inconsistency. A full list of the edit specification rules was created by the census team and is recorded in Annex B of this report.

After editing, the data contains item non-response, either because the respondent failed to provide a required answer or because of the editing process. The NISR has used standard (hot-deck and cold-deck)

donor-based methods to impute for the item non-response on a variable-by-variable basis. Such an approach preserves the marginal distribution of a variable, conditional on the variables used to identify the donor. Still, it can damage multivariate relationships as different donors can provide imputations for the item

non-response of related questions within a single individual.

Note that for some variables where it was not obvious to identify a correction rule, we decided to record a "missing" value. These "missing" values end by 9s (in a two digits variable, 99=Missing) and are identified in the data dictionary as "Missing."

5.4 Data Editing Report

From the internal consistency check, a minimal number of issues were edited, and imputation rates for individual questions are generally a fraction of one percent. The corrections with many cases edited came from the issues identified during the field supervision. For instance, considering the question, "How many years

has [NAME] been living continuously in [District]?" some enumerators recorded the person's age if the person's residence had not changed since birth. However, the instruction in the questionnaire was to write 888 if the person never moved. Therefore, 8.0% of the resident individuals for this issue have been fixed.

5.5 Concluding Remarks On The Post Enumeration Phase

A close examination of the entire enumeration phases and processes from the initial planning through the enumeration phase and the final phase indicates that use of CAPI greatly improved data quality by eliminating potential weak point and errors associated with data entry in the pen-and-paper personal interview (PAPI) as was done in the previous censuses. As a result, far less editing and imputation was done for the RPHC5 compared to the previous censuses of 2012, 2002 and

others. The best approach in data collection is to eliminate sources of error before the actual enumeration rather than taking measures to later correct them. This approach was adopted for the 2022 Population and Housing Census and thus contributed to quality of the data. For the few identified cases, the census team has successfully used edit and imputation rules to fix the internal consistencies. The full imputation report is presented in Annex B of this report.

CHAPTER 6: EVALUATION OF REPRESENTATION

The expectation in a census enumeration is to have 100% coverage of the entire population of a given country or delineated areas. To ascertain the extent of completeness and coverage of the enumeration, the standard practice is to undertake an independent evaluation of the representation of the census. As per the recommendation of the UNSD⁵, an independent evaluation was undertaken to evaluate the census coverage, and the contents of some key variables to identify possible errors and implementation issues that may require adjustment in the data. These processes are also important to document lessons for future censuses. The Dual System Estimation (DSE) was used for the evaluation. NISR has implemented this approach for the fourth time in the 1991, 2002, 2012 and now 2022 rounds of Population and Housing Censuses.

6.1. Design And Conduct Of The Pes

To ensure the representativeness of PES results, a stratified single-stage sample design was used. The sampling frame was based on the cartographic data from the census mapping done in 2020 with a total number of 24,347 enumeration areas, where 180 EAs were drawn for the PES, stratified by district, sector and urban/rural areas. Within each district, 6 EAs were selected using systematic random sampling technique.

Institutional homes, floating and homeless populations were not included in the PES sample. This is the common practice in most countries. The PES only covered the private household population and not the individual residents in institutional households. In the field, the PES enumerators went through a process similar to the census enumerators to identify their EAs 'on-the-ground' using the EA map loaded on electronic devices, and then carried-out a comprehensive listing of the whole EA completely independently of the listing done for the census. The PES enumerators then obtained responses from all listed households. They first collected the basic demographic characteristics of all the usual residents of all households as per the stated PES day, that is around one month after Census Night. Thereafter, they established who amongst those individuals were also usual residents (present or absent) on Census Night so that in-movers to the household since the census could be excluded. Second, they collected the same data on all individuals that were usual residents (present or absent) on Census Night that were no longer usual residents to ensure that out-movers were included. The very short time between Census and PES (around one month) was adopted to minimize issues regarding in movers and out movers.

For the PES analysis, a comparison of census and PES records by matching was done at the individual level. It was done based on variables that are most likely to facilitate an optimal identification of people in both census and PES datasets. These are household identification (HHID), names, age, sex, marital status and relationship to the head of household. A computer-based algorithm was developed in Python programming language to perform the matching process. Field visits and telephone calls were done during reconciliation to find additional matching records and understand the reasons behind the unmatched data.

⁵ Post Enumeration Surveys – Operational guidelines, New York, 2010, UNSD.

6.2 Approach To The Estimation Of Coverage

The estimation of the census coverage used the Dual-System Estimation (Table 6. 1:) as recommended by the United Nations.

Table 6. 1: **Dual-System estimation technique**

| | In Census | Out of Census | Total |
|------------|--------------------|--------------------|--------------------|
| In PES | \widehat{N}_{11} | \widehat{N}_{12} | \widehat{N}_{1+} |
| Out of PES | \widehat{N}_{21} | \widehat{N}_{22} | \widehat{N}_{2+} |
| Total | \widehat{N}_{+1} | \widehat{N}_{+2} | \widehat{N}_{++} |

Where;

\widehat{N}_{11} is an estimate of the number of people counted in both the census and the PES

\widehat{N}_{12} is an estimate of the number of people counted only in PES

\widehat{N}_{21} is an estimate of the number of people counted only in the census

\widehat{N}_{22} is an estimate of the number of people missed by both the census and the PES

\widehat{N}_{+1} is an estimate of the number of people counted correctly in the census

\widehat{N}_{1+} is an estimate of the number of people counted correctly in the PES

\widehat{N}_{++} is an estimate of the total number of people reported in both the census and the PES

The following are key concepts of Dual-System Estimation (DSE):

1. **Matching Rate:** This is the matched population between the census and PES relative to the PES population.

$$\text{Matching rate} = \frac{PES_{pop}}{Matched_{pop}}$$

2. **DSE:** This is the population estimated from the PES multiplied by the population from the census after correcting for erroneous inclusions and divided by matched population between the census and the PES. For each enumeration area A, we use dual-system estimation to calculate the estimate of the true population, post-stratified by age-sex group and urban/rural geography type.

$$DSE_{AHE} = \frac{(PES_{AHE}) \times (CEN_{AHE} - ErronInclusion_{AHE})}{MatchedNonMovers_{AHE} + MatchedOutMovers_{AHE}}$$

Where,

- DSE_{AHE} is the estimate of the total population in enumeration area A, with age-sex group H and urban/rural E
- PES_{AHE} is the PES count of persons in enumeration area A, with age-sex group H and urban/rural E
- CEN_{AHE} is the Census count of persons in enumeration area A, with age-sex group H and urban/rural E
- $ErronInclusion_{AHE}$ are persons erroneously included in enumeration area A, with age-sex group H and urban/rural E
- $ErronInclusion_{AHE}$ are persons erroneously included in enumeration area A, with age-sex group H and urban/rural E
- $MatchedNonMovers_{AHE}$ are matched non-movers in enumeration area A, with age-sex group H and urban/rural E
- $MatchedOutMovers_{AHE}$ are matched out-movers in enumeration area A, with age-sex group H and urban/rural E

3. **Net coverage error rate** is the total net error relative to the dual-system estimate of the true population; that is, divided by DSE.

$$\text{Net coverage error rate} = \frac{\text{Net Coverage Error}}{\text{TruePop}}$$

4. **The Net coverage rate** is the complement of the Net Coverage Error Rate. It is equal to 100-Net Coverage Error Rate.

6.3 Summary Results Of Coverage Assessment

As shown in Table 6. 2, the net coverage rate at the national level is 98.7%. The highest net coverage rate is observed in Northern and Western Provinces with 99%, while the lowest Matching rate is observed in the City of Kigali with 96.9%. Rural areas have a greater net coverage rate compared to urban areas, with 99.0% and 97.7% respectively. In age groups, the highest matching rate is observed in the age group 45-59 years with 99.1%, while the lowest matching rate is observed in the group 15-29 years with 97.9%. Females have a greater net coverage rate compared to males with 98.9% and 98.4% respectively.

Table 6. 2: Net Coverage Rate (%) by Province, age group, Sex and area of residence

| Rwanda | Male | Female | Urban | Rural | Total |
|-------------------|------|--------|-------|-------|-------|
| | 98.4 | 98.9 | 97.7 | 99.0 | 98.7 |
| Age groups | | | | | |
| 0-4 | 98.5 | 98.8 | 97.7 | 99.0 | 98.6 |
| 5-14 | 98.8 | 98.8 | 98.1 | 99.1 | 98.8 |
| 15-29 | 97.5 | 98.3 | 96.7 | 98.3 | 97.9 |
| 30-44 | 98.4 | 98.9 | 97.9 | 99.0 | 98.7 |
| 45-59 | 98.8 | 99.5 | 98.4 | 99.4 | 99.1 |
| 60+ | 98.7 | 99.3 | 97.6 | 99.5 | 99.0 |
| Province | | | | | |
| City of Kigali | 95.9 | 97.8 | 96.8 | 97.6 | 96.9 |
| Southern Province | 98.2 | 98.9 | 98.2 | 98.6 | 98.5 |
| Western Province | 98.8 | 99.2 | 98.5 | 99.2 | 99.0 |
| Northern Province | 98.9 | 99.1 | 97.1 | 99.2 | 99.0 |
| Eastern Province | 99.2 | 99.1 | 98.2 | 99.3 | 99.1 |

Source: Post Enumeration Survey, 2022(NISR)

The net coverage error rate at the national level is 1.3%. A less coverage error rate is observed in rural areas (0.97%) compared to urban areas (2.26%). Provincial patterns indicate that City of Kigali has the highest coverage error rate (3.1%) while Eastern Province has the least rate (0.9%) (Table 6. 2). The difference in net coverage error rates between females (1.07%) and males (1.56%) is 0.5 percentage points (Table 6. 3). The evaluation shows that under-coverage rate for the RPHC5 is minimal, thereby affirming the 2022 Census to be of high quality in terms of coverage. This result explains the great effort made towards the smooth implementation of the 2022 Population and Housing Census.

Table 6. 3: Type of Census Coverage Errors (%) by main population Sub-groups

| Type of Census Coverage Errors | Rwanda | Urban | Rural | Male | Female |
|--------------------------------|--------|-------|-------|------|--------|
| Census Net Coverage error rate | 1.31 | 2.26 | 0.97 | 1.56 | 1.07 |
| Under Coverage rates | 1.51 | 2.45 | 1.17 | 1.8 | 1.22 |
| Over Coverage rates | 0.19 | 0.19 | 0.19 | 0.23 | 0.14 |
| Gross Coverage error rates | 1.78 | 2.79 | 1.41 | 2.15 | 1.41 |

Source: Post Enumeration Survey, 2022(NISR)

CHAPTER 7: EVALUATION OF MEASUREMENT AND REPRESENTATION

Information obtained in a census in terms of its contents and representation should be of high quality. The effectiveness of government policies and programmes, to a very large extent, depends on the quality of data used for planning. To ensure the quality of official statistics, the UN recommends the evaluation of measurement and representation of census data. The preparation for the RPHC5 outlined in Chapter 3, the enumeration phase outlined in Chapter 4, the post-enumeration phase outlined in Chapter 5, and the independent coverage check in Chapter 6 all point to a final census database with both excellent representation and good coverage. However, the final

check on quality of key variables is important. It is necessary to confirm whether the obtained numbers are plausible in line with the theoretical expectation, and whether they are consistent with the patterns and information available from other sources; and whether there are any internal inconsistencies in the numbers such as obvious age heaping or peculiar sex ratios. In this section we first consider the basic structure of the population and then look at the data collected on fertility, mortality, migration, as well as selected socio-economic variables, such as education, economic activity, marital status, and life expectancy.

7.1 Population Size And Structure

As presented in Chapter 6, the RPHC5 has a high overall coverage. It is expected that the total population figures and distributions are also of high quality. This is confirmed by the total population figures in Table 7.1 showing sensible levels of growth between 2012 and 2022 for the total population and populations by sex and

urban-rural distribution. The overall growth rate of 2.3% per annum is consistent with a population that has a declining fertility and declining mortality positively contributing to growth, while the impact of fertility decline is being offset by a young age structure.

Table 7.1: Evolution of the size of the population between 1978 and 2022

| Year of census and intercensal growth rate | Rwanda | | | Urban | | | Rural | | |
|--|-------------------------|-----------|------------|-----------|-----------|------------|-----------|-----------|------------|
| | Male | Female | Both sexes | Male | Female | Both sexes | Male | Female | Both sexes |
| | Year of the Census | | | | | | | | |
| 1978 | 2,363,177 | 2,468,350 | 4,831,527 | 122,784 | 99,943 | 222,727 | 2,240,393 | 2,368,407 | 4,608,800 |
| 1991 | 3,488,612 | 3,668,939 | 7,157,551 | 207,490 | 183,704 | 391,194 | 3,281,122 | 3,485,235 | 6,766,357 |
| 2002 | 3,879,448 | 4,249,105 | 8,128,553 | 727,172 | 645,432 | 1,372,604 | 3,152,276 | 3,603,673 | 6,755,949 |
| 2012 | 5,064,868 | 5,451,105 | 10,515,973 | 891,806 | 845,878 | 1,737,684 | 4,173,062 | 4,605,227 | 8,778,289 |
| 2022 | 6,429,326 | 6,817,068 | 13,246,394 | 1,851,588 | 1,837,412 | 3,689,000 | 4,577,738 | 4,979,656 | 9,557,394 |
| | Intercensal growth rate | | | | | | | | |
| 1978-1991 | 3.0 | 3.1 | 3.07 | 4.12 | 4.79 | 4.43 | 3.02 | 3.00 | 3.00 |
| 1991-2002 | 1.0 | 1.3 | 1.2 | 12.08 | 12.10 | 12.09 | -0.36 | 0.30 | -0.01 |
| 2002-2012 | 2.7 | 2.5 | 2.6 | 2.1 | 2.7 | 2.4 | 2.8 | 2.5 | 2.7 |
| 1978-2012 | 2.3 | 2.4 | 2.3 | 6.0 | 6.5 | 6.2 | 1.8 | 2.0 | 1.9 |
| 2012-2022 | 2.41 | 2.26 | 2.34 | 7.58 | 8.07 | 7.82 | 0.93 | 0.78 | 0.85 |
| 1978-2022 | 10.5 | 10.7 | 10.6 | 31.2 | 33.8 | 32.4 | 7.4 | 7.7 | 7.6 |

Source: Rwanda Population and Housing Census 1978, 1991, 2002, 2012, 2022.

The census coverage by age and sex is high so we expect the basic age-sex structure of the population to be of high quality. This is confirmed by the population pyramid in

Figure 7.1 and the line graph in Figure 7.3, representing the overall population in standard five-

year age-groups. It displays the overall shape we would expect. However, looking at the data by age-groups can hide other data quality issues such as heaping of ages on single digits. Therefore, single year pyramid and single-year graphical presentation are presented in Figure 7.2 and Figure 7.4, respectively. The two figures

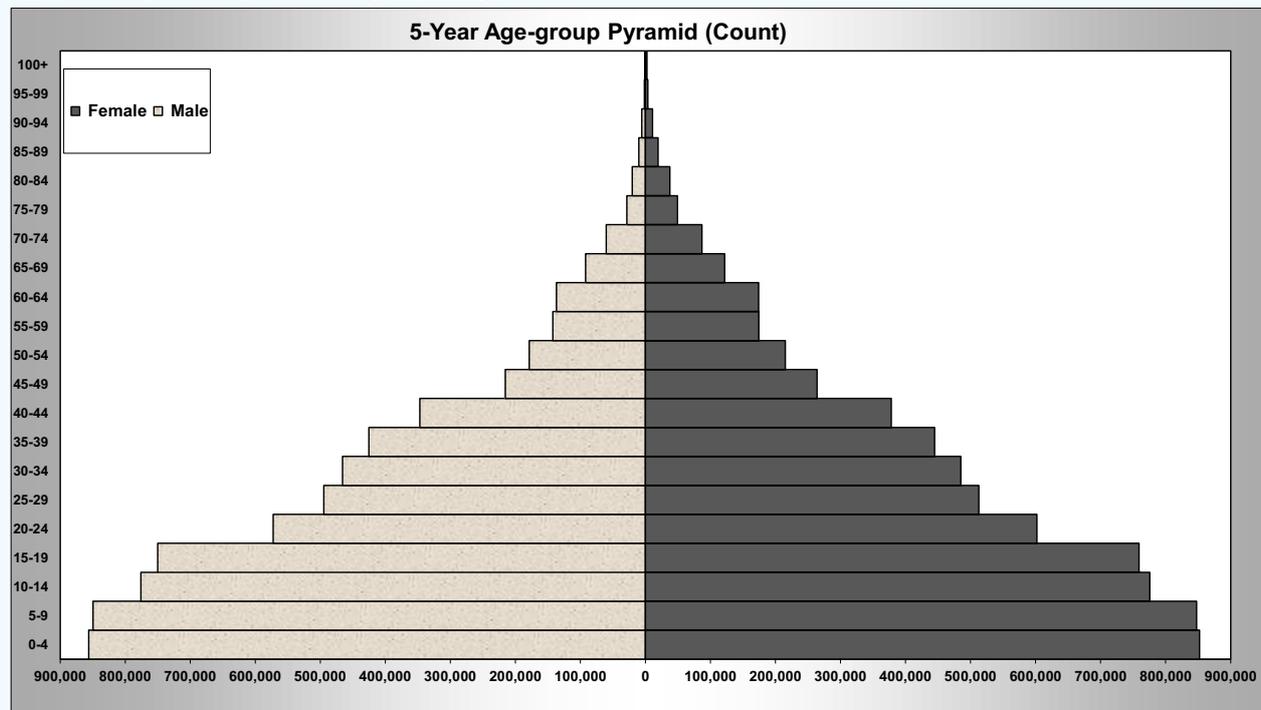

indicate some evidence of age heaping, possibly due to the rounding of ages, particularly on terminal digits 0, 5 and a few even numbers like 2. Heaping on the terminal digit 2 for age would be consistent with heaping on the year-of-birth at 0 and the census being in a year ending in 2. Figure 7.2 and Figure 7.4 show a zig-zag pattern which deviates from the theoretical expectation of a population distribution that gradually declines due to effect of mortality in successive older ages. On the other hand, a closer look at

Figure 7.1 and Figure 7.3 indicates a smoother age distribution that gradually declines according to the expected pattern. Juxtaposing evidence from the pictorial presentations in single-year and 5-year age group suggests a situation of rounding of ages mainly within the same age groups. The 5-year age groups seem more appropriate for use as they appear to correct the systematic measurement errors arising from rounding of ages.

Further and as one would expect, the population distribution by sex indicates that females (51.5%) are slightly more than males (48.5%). The overall population structure is further presented by urban-rural

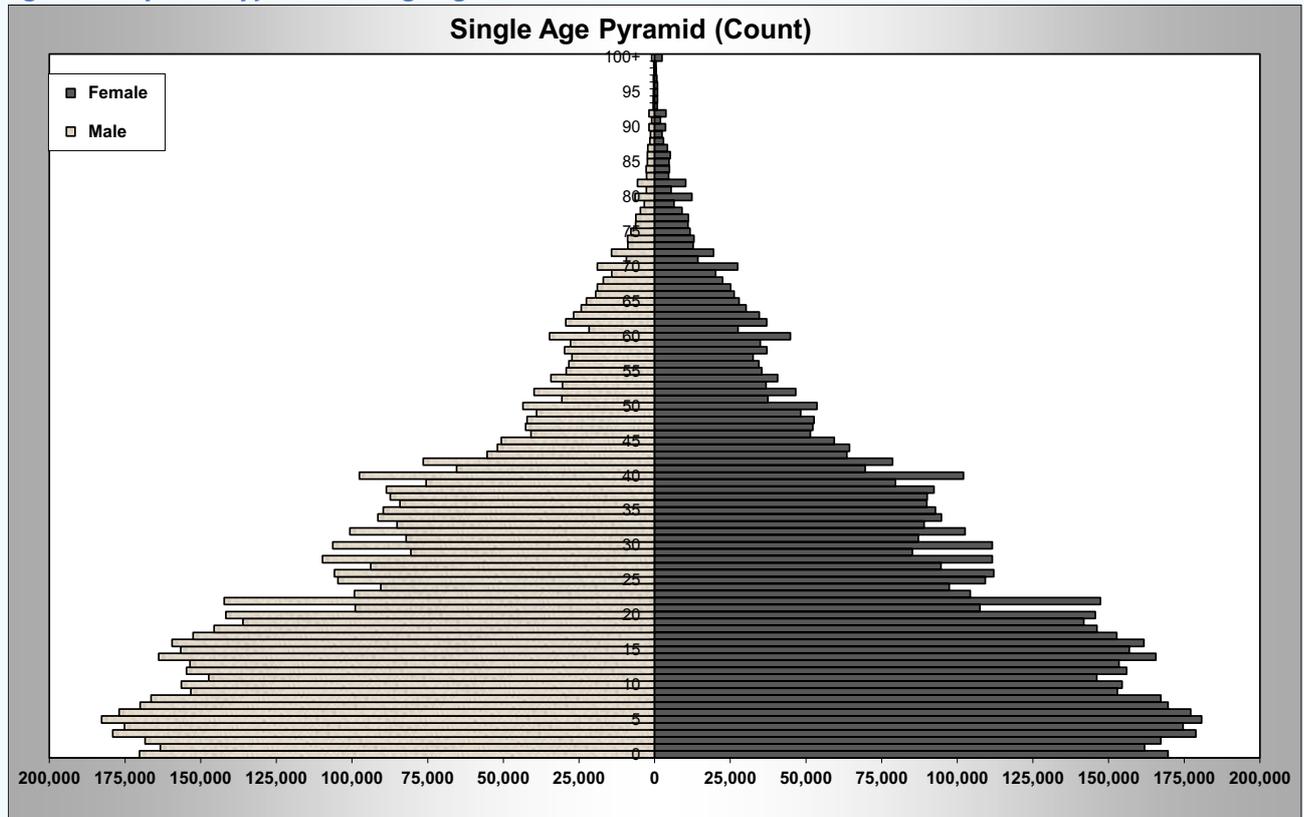

distribution (Table 7.2). Population distributions in Table 7.2 and Table 7.3 show that the rural population is still predominant in the country, though with considerable increase in urban population by 7.8% over the inter-censal period of 2012-2022. Rural-urban population distribution by age and sex indicates adequate reporting of male and female births, though there is some evidence of underreporting of male births. The sex ratio continues to decline gradually with increasing ages, thus demonstrating excess mortality among males compared to female population. There is some evidence of sex imbalance in age group 15-19 (87.5) suggesting underreporting of males at this age group, perhaps they were absent from homes for attending tertiary educational institutions or other activities. As would be expected, there is sex imbalance in favour of males in age groups 25-29 to 55-59 showing more males than females in urban areas with corresponding lower sex ratio in rural areas, which can be explained by the economic reason of labour migration to cities.

The overall growth rate reported in Table 7.1 for the inter-censal period seems plausible, but we can also consider the progression of the population from 2012 to 2022. Figure 7.8 shows the proportion of an age-group in 2012 that is surviving in 2022. So, for example, it is the ratio of 10 to 14 year-olds in 2022 to 0- to 4-year-olds in 2012. The general pattern is sensible with male survivorship declining more than female for the older age-groups due to higher mortality among males than females. There appears to be some anomaly with the

survivorship of female population aged 0-4 which appears lower than the expected pattern. While the 2012 census indicated evidence of some temporary international migration in that the count of those actually present on census night (residents and visitors) was less than the total count of residents (present and absent), the reverse is the case in 2022 census, as the number of total residents (present and absent) exceeded the number counted on the census night (residents and visitors)

Figure 7. 5 Survivorship from 2012 to 2022(grouped age)

Looking at the sex ratios more generally, Table 7. 3 presents the sex ratio by age-group for Rwanda as a whole, and by urban-rural distribution. Looking at the sex ratios for Rwanda, although slightly higher than it was in 2012, it is clear that the ratio of 100 from the youngest age-group looks somewhat low compared to the expected sex ratio at birth of 103 to 107. In general, the pattern of decline of sex ratio in successive age groups is reasonable but is lower than would be expected. Of course, the sex ratio is very sensitive to the usual pattern of excess male under-coverage in

censuses, but this is often in the young adult ages. Under-coverage of children is more usually either non-differential with respect to sex or more prevalent for female children. The impact of the past history of Rwanda is evident in the considerable decline in sex ratio for the population in their late 40s and early 50s. Further, a comparison of sex ratio for urban and rural areas indicates the expected impact of male economic migration and greater sex imbalance in terms of more males in urban areas during the main years of economic activity, with a corresponding drop for the rural area.

Table 7. 3: Sex Ratios by 5-year age-group

| 5-year age-group (Years) | 2002 | | | 2012 | | | 2022 | | |
|--------------------------|--------|-------|-------|--------|-------|-------|--------|-------|-------|

Source: Rwanda Population and Housing Censuses 2002, 2012, 2022

The comparison of sex ratios for the three censuses (Table 7. 3) indicates a better reporting of age-sex data in 2022 census compared to 2002 and 2012. The general age-sex structure of the population in RPHC5 is sensible, although there is some suggestion of slight under-coverage of 0-4-year-olds and an apparent systematic under-reporting of males. This second issue is also confirmed by the PES, which estimates the coverage of males to be slightly lower than females, although not by enough to fully explain the sex ratio effects seen here.

Figure 7.7 shows an obvious spike at age 22, which relates to a mini baby boom in 2000 and a spike that was

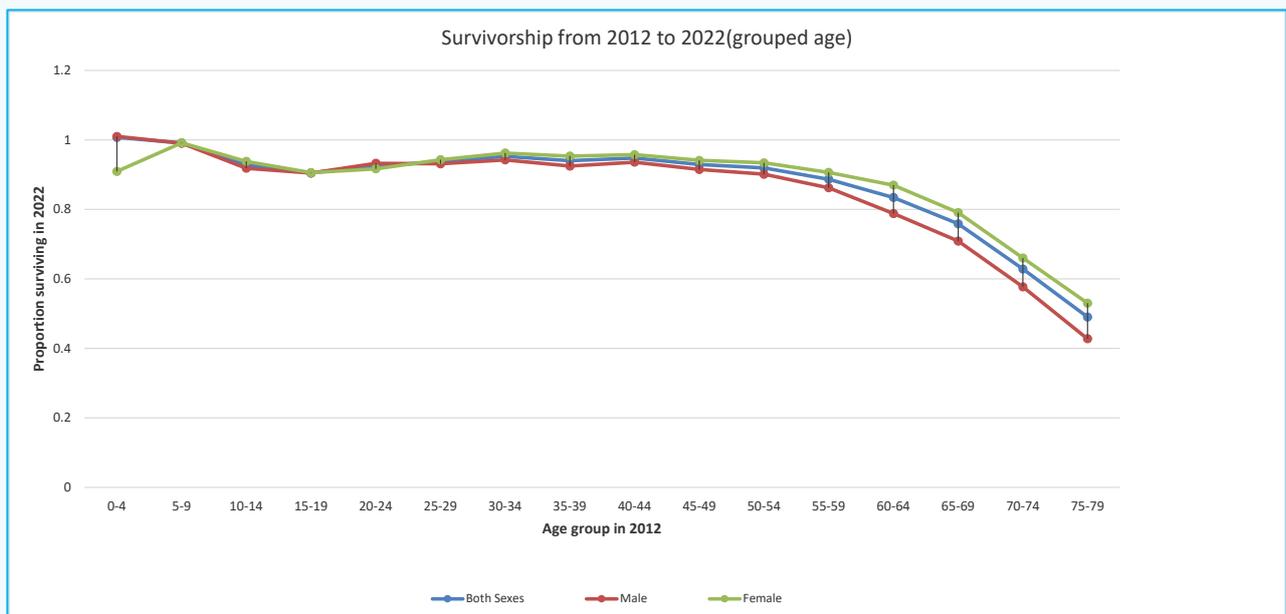

observed at age 12 according to the 2012 census. We can also look at the 10-year survivorship from 2012 to 2022 by single year age. Figure 7.7 demonstrates a zig-zag pattern but as age increases, we start to see declines in survivorship with males below females. As earlier pointed out, we can see a high number of 22-year-olds which also corresponds to an unusually high number of 12-year-olds in 2012 thus signifying evidence of a mini baby-boom in 2000. Again, the pictorial presentation of 10-year survivorship from 2012 to 2022 in grouped age shows a much smoother pattern, thus confirming the evidence of age heaping in single-year age data.

Figure 7.7 Survivorship from 2012 to 2022 (single years)

Source: Fifth Rwanda Population and Housing Census, NISR 2022.

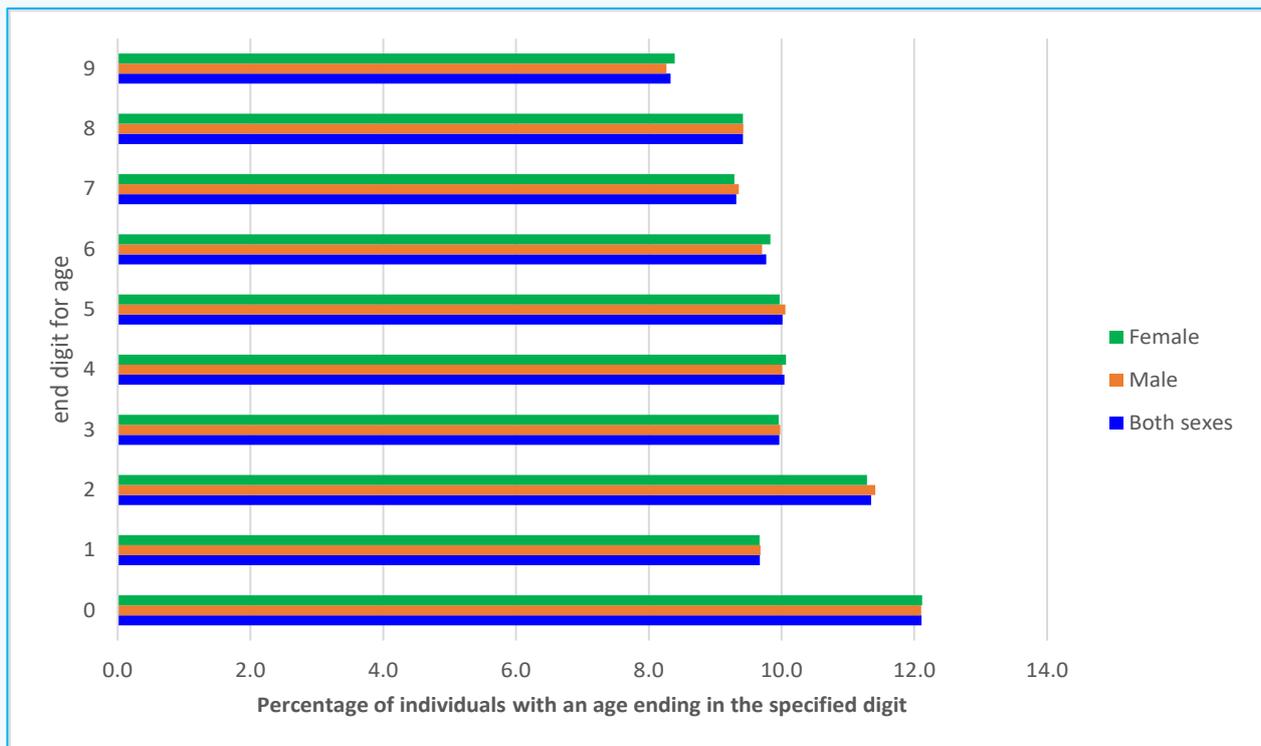

Figure 7.8 Survivorship from 2012 to 2022 (grouped age)

Source: Fifth Rwanda Population and Housing Census, NISR 2022.

Less survivorship among females aged 0-4 compared to males suggests excess mortality among females – a rare scenario, or alternatively a possible under-reporting of males in the previous census. Putting this together with the population pyramid and the line graph in Figure 7.2 and Figure 7.6 respectively suggests that there were some irregularities in age reporting in 2022, although a comparison of the observed patterns of age-sex reporting in 2022 with the two previous censuses (2002 and 2012) signifies an improvement in the accuracy and quality of age-sex data.

Figure 7.9 Percentage of individuals with an age ending in the specified digit

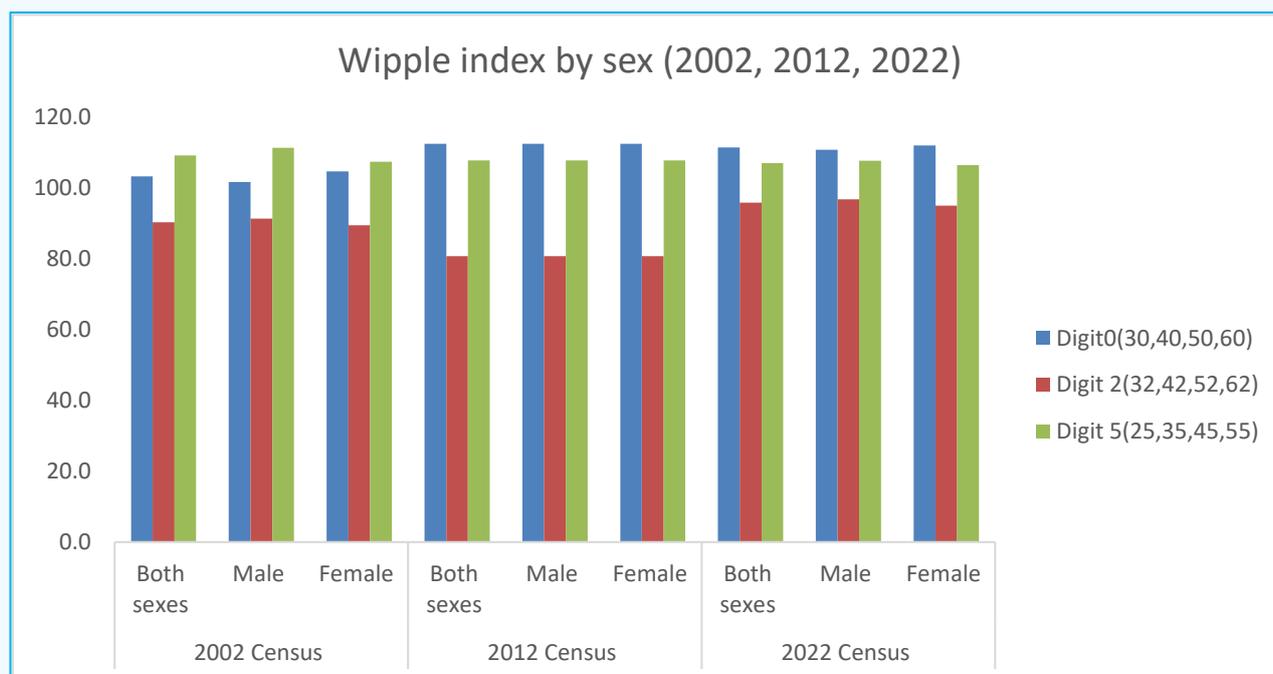

Source: Fifth Rwanda Population and Housing Census, NISR(2022).

While looking at patterns in the single years, we can overly concentrate on a single age issue and neglect the overall pattern. For this, more summary measures can be useful. Figure 7.9 shows the distribution of end digits from zero to nine (for those with reported age from 0 to 99) and pictorially shows some preference for 0 when reporting age either in completed years (0 in the figure) or by year-of-birth (2 in the figure). To further evaluate the age data, more summary measures (Whipple's, Myers' and UN age-sex accuracy indices) are considered. The Whipple's index focuses on specific digits, while Myers' index and the UN age-sex accuracy index look for general evidence of age-heaping (and sex misreporting in the case of the UN) across all the terminal digits 0-9. The trend in summary indices is presented to compare the quality of age data for the last 3 censuses (2002, 2012 and 2022). Whipple's index is employed in Figure 77.10 to explore the extent of age heaping in the data with respect to 0, 2, and 5 for ages 23 to 62⁶. Whipple's index shows a consistent pattern of heaping for terminal digits 0 and 5 for the last three censuses, however, a greater heaping was observed for terminal digit 2 in 5RPHC compared to the two previous censuses.

⁶The UN standard is 23 to 62, allowing the exploration of digit preference with respect to 25, 35, 45, and 55; or 30, 40, 50 and 60.

Figure 7. 10 Whipple index by sex for the last three censuses (2002, 2012 and 2022)

Source: Rwanda Population and Housing Census 2002, 2012, 2022

Table 7. 4: UN recommendations for interpreting Whipple's index

| | |
|-------------------------|------------------------|
| WI < 105 | Highly accurate |
| 105 ≤ WI ≤ 109. | Fairly accurate |
| 110 ≤ WI ≤ 124.9 | Approximately accurate |
| 125 ≤ WI ≤ 174.9 | Roughly accurate |
| WI ≥ 175 | Very Roughly accurate |

The values for the Myers' Index in Table 7. 5 are encouraging with zero representing no age heaping, while the UN measures are slightly more than 20; where less than 20 is desirable for evidence of accurate recording of age and sex and over 40 is considered highly inaccurate. Comparison of Meyers' index and UN summary measures for 2002 to 2022 (Table 7. 5) signifies an improvement in the quality of age reporting in the RPHC5. The overall Myers' blended index for the 2022 census indicates improved quality and less age heaping compared to the 2002 census. Also, the UN age-sex accuracy index (Table 7. 5) for the RPHC5 shows a more accurate reporting of age data compared to the previous

censuses, with UN's recommendation of less than 20 as desirable, 22.9 was obtained from the 2022 census. From the evaluation of age data, we can conclude that the age data of RPHC5 is of high quality, although, as earlier reported, the distribution of ages in single year suggests some evidence of rounding of ages mainly within age groups. Thus, the use of 5-year age group may be preferred, where applicable, rather than the single-year age distribution as the former appears to correct the systematic measurement errors arising from rounding of ages. This is because avoidance of a terminal digit in preference for another often occurs within the same five-year age-group.

Table7. 5:Myers index by sex for the last three censuses (2002, 2012 and 2022)

| Myers Blended Index Calculation 2002-2022 | | | | | | | | | |

Source: Rwanda Population and Housing Census 2002, 2012, 2022

Pulling together the information in this Chapter, there is some evidence of slightly lower under-reporting of males compared to females, and this is confirmed by the PES data. The under-reporting is especially true for children but as we move into adult ages it could also be partly related to a work migration pattern and PES coverage of young adult males, particularly ages 15-44, is slightly lower than other male groups. There is apparent evidence of under-reporting of very young children in the population pyramid, but this has to be weighed against a population that is experiencing both fertility and mortality decline. The heaping on the

preferred terminal digits does not potentially create any problem particularly when grouped age structure is used as shown in

Figure 7. 1 and Figure 7.3. Overall, the age-sex structure in RPHC5 is sufficiently well-reported to be used, especially when grouped, and the high level of net coverage indicated by the PES fits with the results. There is no proposal to adjust the age-sex structure based on either the PES results or the demographic analysis presented here.

7.2 Fertility Data

Fertility data obtained through censuses are prone to possible errors, including coverage error or systematic misreporting of information. Such errors may vary in size and nature depending on the quality control measures put in place during enumeration and data processing. Evaluation of fertility data from censuses is an important quality assurance measure (US Census Bureau, 2019). This section focuses on the basic data

reported in the fertility section of the household questionnaire. As a simple check on the completeness of fertility data, it is expected that, after accounting for the impact of infant mortality, the number of recent births (i.e., births in 12 months before the census) should be about the same as the size of the resident population aged less than 1 year on the Census Night. A comparison of recent births with the size of the resident population

aged less than 1 year on the Census Night (Table7. 7) suggests that recent births were well reported, but with some evidence of possible underreporting of infant deaths. This is because the number of recent births exceeded the resident population aged less than 1year by 7% (Table7. 7). If there is no significant underreporting of infant deaths, the difference between recent births and resident population aged less than 1year should be approximately the same as the reported number of infant deaths, except there is significant out-migration of babies which is highly unlikely in the

prevailing situation. Table7. 8 shows that the lifetime reporting of fertility in RPHC5 looks plausible and somewhat better than those reported in the RPHC4, when sex ratios are examined, although we can observe from the lower sex ratio some evidence of under-reporting of male births in the younger age of mother, particularly at age group 10-14. Underreporting of births is expected at the younger ages of mother like 10-14, not just for the male births, but also for females. The lifetime reports of fertility for this group of young mothers will be mostly associated with the most recent fertility

.Table7. 7: Number of births in the past 12 months, and number of resident population less than 1

| | Male children | Female children | Both sexes |
|--|---------------|-----------------|------------|
| Number of births reported in past 12months | 186,497 | 178,052 | 364,549 |
| Number of 0-year olds in the population | 170,246 | 169,654 | 339,900 |

Using the reported fertility, we can estimate the crude birth rate and general fertility rate. Technically, the denominator should be adjusted back from the Census Day to six months earlier⁸ but this has not been done here as the aim is to judge the likely quality of the fertility data, not present the final fertility analysis of the thematic report. Similarly, as the aim is to study the trend in the indicators over a short time interval the indicators are not standardised for age.

Figure 7.9 presents both rates and for comparison figures from the 2002, 2012 and 2022 censuses. Additionally, relevant fertility indicators from other sources, that is, the sequences of Demographic and Health Surveys (DHSs) are included for comparison purpose.

⁷ In the RPHC4, the target population for the questions on fertility were females aged 12 years and above, while in the RPHC5, the target population were females aged 10 years and above.

⁸This can be done by either using the inter-censal growth rates to interpolate backwards or by using the births and deaths data with an assumption of a uniform distribution over 12 months. This would assume that half the births and half the deaths reported for the 12-month period would have occurred at six months prior to the census.

Table 7. 9 :Evolution between 1992 and 2012 of basic fertility measures

| Year (source) | Crude Birth Rate (‰) | General Fertility Rate (‰) | Mean Parity at end of childbearing |
|---------------|----------------------|----------------------------|------------------------------------|
| 1992 (DHS) | 41.0 | 197 | 7.7 |
| 2000 (DHS) | 39.2 | 180 | 6.8 |
| 2002 (PHC) | 41.2 | 162 | 7.06 |
| 2005 (DHS) | 43.2 | 190 | 6.6 |
| 2007-08 (DHS) | 39.2 | 179 | 6.0 |
| 2010 (DHS) | 34.4 | 151 | 5.9 |
| 2012 (PHC) | 28.5 | 113 | 5.60 |
| 2014-15(DHS) | 32.6 | 141 | 5.8 |
| 2019-20(DHS) | 31.8 | 134 | 5.0 |
| 2022(PHC) | 27.8 | 105.5 | 5.9 |

Source: ICF International, 2022, MEASURE DHS STAT compiler - <http://www.statcompiler.com> –accessed October 7, 2022, for the DHS results; 2002 Census results as published in National Census Service (2005). Fourth Rwanda Population and Housing Census as published by the NISR. Notes: (1) Rates from the DHS are based on averaging the three years prior to the survey date recorded in the table, while mean parities at the end of childbearing are based on ages 40 to 49 rather than 45 to 49 for the two censuses.

From Table 7.9 we can see that fertility has been declining both in terms of the crude birth rate (CBR) and the general fertility rate (GFR) since the early 2000s. Comparing CBR and GFR from the RPHC5 with those obtained from the last two censuses and the previous Rwanda DHSs indicates a continuous decline in fertility, although earlier reports indicate an under-reporting of recent births during the RPHC4. As shown in Table 7.9 results on mean parity at the end of childbearing show some evidence of fertility stall, in that the reported mean parity was around 5.8 to 6.0 over a period of 12 years (i.e., the period between 2007/08 DHS and RPHC5). A comparison of the pattern of ASFR for RPHC5 and RPHC4 (Figure 7.11) suggests a situation of

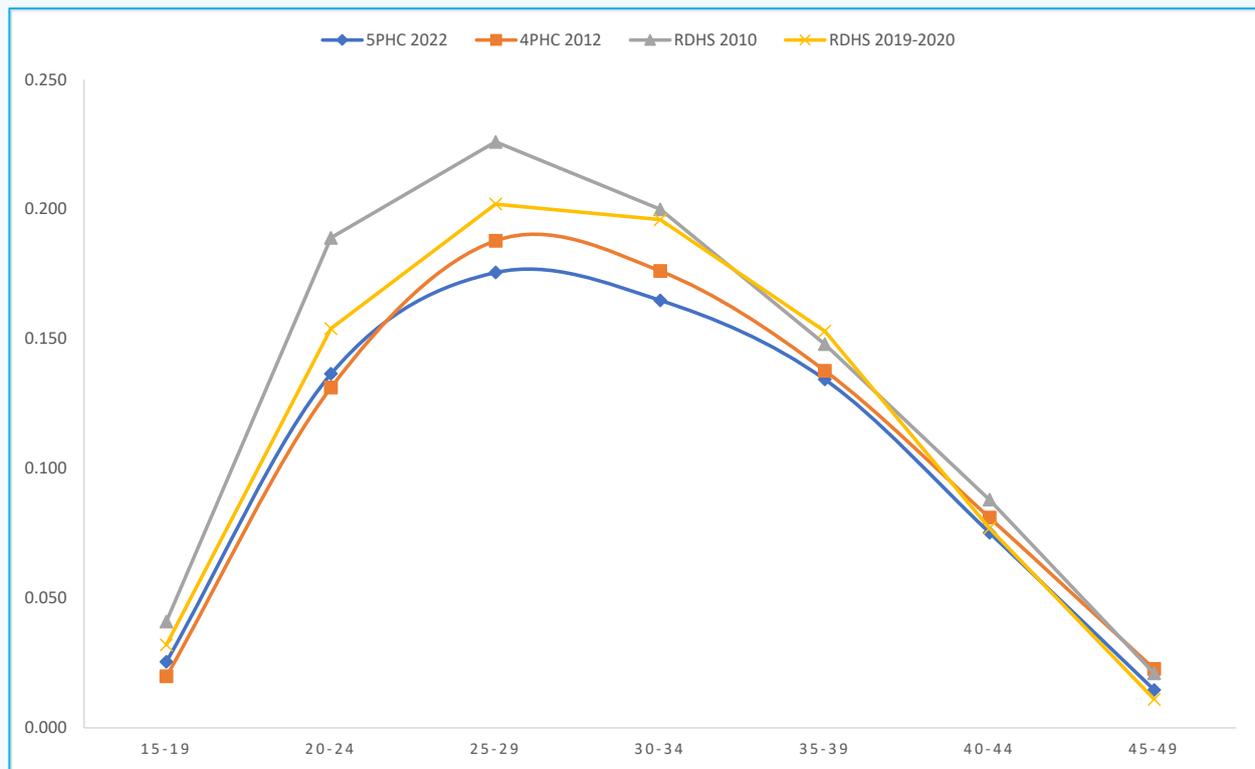

inaccurate/over-reporting of current fertility by young mothers ages 15-24 and older women aged 35 and above. The figure shows a better reporting of fertility for women ages 24-34, thus corroborating the assumptions of more accurate fertility reporting for this group of women compared to others, as has been reported in the seminal work of Coale and Brass (1968) and others (Adedini, 2014, Mba, 2013). Generally, we can conclude that both the current births and lifetime fertility are of high quality and there would be no need for adjustment of fertility level. One important point to take note from this section is the evidence of some underreporting of infant mortality.

7.3 Mortality Data

Accurate mortality estimations are essential for public health planning (Makinde *et al*, 2021, Salzberg *et al*, 2019) and for monitoring performance of national development goals such as the Rwandan Vision 2050. While civil registration and vital statistics (CRVSs) are the veritable data sources for estimating mortality rates, CRVSs are incomplete in many sub-Saharan African countries (Adedini *et al*, 2021). In the absence of high-quality vital registration data, population census serves as important data source for estimating mortality rates of the population. However, there is always a concern that mortality data from census may be under-reported, and also considering that the questions come at the very end of the questionnaire, thus raising further issues regarding whether enumerators properly ask the questions on mortality.

First, after accounting for the effect of infant mortality, it is expected that the number of recent births should be

about the same as the count of resident population aged less than 1 year, unless there has been a significant international in-migration of babies (in the case of more births reported) or a considerable out-migration of babies (in the case of less births reported). A comparison of recent births and resident population under 1 year of age as shown in Table 7. 11 indicates that the former exceeds the latter by 7%, with higher disparities for males than females (8.7% vs. 4.7%). This difference should approximately be the same as the reported number of infant deaths, except there was a significant out-migration of babies which is highly unlikely in the prevailing situations. However, this difference, as presented in Table 7. 11, exceeds the reported number of infant deaths by 52.8% (59.8% for males, and 39.3% for females), thus suggesting some evidence of underreporting of infant mortality

Table7. 11: Summary data relating to numbers of births reported in 12 preceding months, 0-year olds in the resident population, and reported infant deaths for 12 preceding months Estimated from direct method

| Measure | Total | Male | Female |
|--|---------|---------|---------|
| Number of infant deaths for 12 preceding months (mortality section) | 11,628 | 6,528 | 5,100 |
| Number of births reported in past 12months | 364,549 | 186,497 | 178,052 |
| Number of 0-year olds in the resident population | 339,900 | 170,246 | 169,654 |
| Difference between numbers of births reported in past 12 months and resident population <1 year | 24,649 | 16,251 | 8,398 |
| % difference between recent births and population <1 year | 6.8% | 8.7% | 4.7% |
| Difference between the excess of recent births over resident population <1 year and number of infant deaths for12 preceding months | 13,021 | 9,723 | 3,298 |
| % difference between the excess of recent births over resident population <1 year and number of infant deaths for12 preceding months | 52.8% | 59.8% | 39.3% |

Source: Rwanda Population and Housing Census 2012 and 2022; *Unadjusted results, **Adjusted results constructed from indirect methods as published by NISR (2022).

Results presented in Table 7.12, which compare the unadjusted and adjusted crude death rates (CDR) for 2012 and 2022 censuses indicate some evidence of improved quality of death reporting for RPHC5, albeit, underreporting of mortality data persists in 2022. This is because the crude death rate from RPHC5 is also low; though government's interventions in the health sector and the improvement in living standard of people is expected to have brought about some reduction in mortality rates in the country. Subtracting the CDR from CBR yields the rate of natural increase (i.e., growth rate in the absence of migration). The difference between the CBR and CDR is 24.1 per 1000 population (or simply 2.41%) which is slightly higher than the growth rate of 2.3%, thus indicating some evidence of possible underreporting of deaths. If the difference between the reported crude rates is sensible with respect to population growth, it implies there is some evidence of underreporting of death at around 11%, assuming there was no considerable out-migration of people from the

country over the inter-censal period. Pulling the evidence together, the under-reported infant deaths and the difference in the crude rates vis-à-vis the population growth translate show some evidence of under-reporting of overall deaths.

Table7. 13 focuses on the specific indicator of infant mortality. The infant mortality rate (IMR) compares deaths to those under one in a year with the births for that year. However, the DHS typically estimates 1q0, the probability that a baby will survive one year. The Lexis Diagram in Figure 7.12 highlights this point. The traditional measure of infant mortality for the year t-1 to t has all the deaths in ABCE in Figure 7.12 as the numerator, and divides by all the births in that year given by AE. The alternative 1q0 is a cohort measure which has all the deaths in ACDE in Figure 7.12 as the numerator and divides by all the births in that year given by AE.

Figure 7.12 Lexis Diagram highlighting the two measures of infant mortality

With the census data, we can calculate the traditional infant mortality rate directly using the deaths to children under one reported in the mortality data to capture the deaths occurring in ABCE, and births reported in the fertility data as the denominator. This can be compared to the q-rates from the DHS, which will be similar to the traditional infant mortality rate unless there has been either a dramatic change in fertility or mortality over a single year period. With the census data,

we can also approximate the infant mortality rate by using the deaths reported in the fertility data. These relate to the triangle ACE in Figure 7.12 which should give a lower number of deaths than those reported in the actual mortality section. The results on the evolution of infant mortality rate by sex are presented in Table 7.13, including the published rates from the DHS and the last two censuses.

Table7. 13: Evolution between 1992 and 2022 of the Infant Mortality Rate (IMR) by sex

Source: ICF International, 2022, The DHS Programme STAT compiler Funded by USAID - <http://www.statcompiler.com> –accessed 15/12/2022 for the DHS results. 2002 Census results as published in National Census Service (2005). Fourth Rwanda Population and Housing Census (2012), Fifth Rwanda Population and Housing Census (2022).

Notes: 1. (*) Rates from the DHS based on averaging the ten years prior to the survey date recorded in the table. (**)The overall rates can also be estimated using just the preceding five years and these are also given in the table to highlight the strength of the overall decline in the most recent years; (2) 2002 and 2012 Census results as published in National Census Service (2005) and NISR (2014), and IMR from 2022 Census are constructed from indirect methods; (3) 2012 results from direct method.; (4) CI: confidence interval

A careful look at the results presented in Table7. 13 shows clear evidence of continuous decline in infant mortality prior to the conduct of RPHC5. Specifically, a comparison of results computed from indirect methods for the previous censuses shows a considerable decline in infant mortality rates (per 1000 live births) from 139 (2002 census) to 48.6 (2012 census). The results also demonstrate that the 2012 Census estimate, i.e., 48.6 is higher (by 52%) than the comparable five-year figure, i.e., 32 for the 2014-15 DHS. The DHS is of course a survey and subject to both under-reporting as well as sampling

error. The results further show that infant mortality rate for 2022 census (31.2 per 1000 live births) computed using direct method is only slightly lower than the rate obtained from the most recent RDHS conducted in 2019-20 (33 per 1000), thus suggesting evidence of better reporting of infant deaths in the RPHC5 relative to the previous censuses. The reductions in infant mortality may be explained by the government's health interventions and programmes for children and pregnant women/nursing mothers across the country.

Table 7. 14: Mismatches between mortality section and fertility section regarding the reporting of infant mortality in past 12 months (%)

| Reporting of infant deaths in past 12 months | 2012 | 2022 |
|---|-----------|-----------|
| Household reports no infant death in past 12 months | 99.0 | 99.5 |
| Household reports infant death both in mortality and fertility sections | 0.1 | 0.1 |
| Household reports infant death in fertility section only | 0.7 | 0.2 |
| Household reports infant death in mortality section only | 0.2 | 0.2 |
| Total (%) | 100.0 | 100.0 |
| Count | 2,406,176 | 3,312,743 |

Source: Fourth and Fifth Rwanda Population and Housing Census.

Table 7.14 presents information on mismatches in the reporting of infant mortality between mortality and fertility sections of the RPHC5. Results in the table suggests evidence of less mismatches in infant death reporting in the RPHC5 compared to the RPHC4, thus suggesting an improvement in infant death reporting in 2022 census. For instance, of all households reporting a death of an infant anywhere on the form, 20% reported the death only in the fertility section of the questionnaire. Similarly, 20% reported the death only in the mortality section of the questionnaire.

Pulling all the evidence together, the results indicate considerable improvement in mortality reporting in the RPHC5 compared to the previous censuses. Nevertheless, as earlier discussed, there is some evidence of under-reporting in the overall mortality level, therefore we recommend the use of indirect techniques to obtain the best attainable mortality estimates, particularly for the thematic report on mortality.

7.4 Selected Demographic And Socio-Economic Indicators

This section presents the results of the assessment of selected key demographic and socio-economic variables. These include marital status, migration, education, and life expectancy.

7.4.1 Marital Status

Marital status is an important characteristic because of its influence on many other variables such as health outcomes, socio-economic position, wealth status and fertility behaviours (Joung, 2010; Adedini *et al*, 2021). Marital status is a key socio-demographic characteristic that is measured in the 2022 census.

Table 7.15 presents percentage distribution of resident population aged 12 years and above by current marital status for both sexes and separately for males and females. Given the young age structure of the country's population, it is plausible that majority of the total population (44.4%), with more males (48.8%) than females (40.4%) are never married. With younger age at first marriage for females than males, the results seem credible that fewer females aged 12 and above are never married compared to males. The results show that

polygyny is very minimal in Rwanda. This seems credible and may be explained by the effect of modernization in the contemporary society. It is observed that widowhood is almost non-existent among males (0.9%), while it is relatively high among females (8.0%), thereby confirming the evidence of excess male mortality relative to females, particularly among the older population. The results also seem credible that levels of divorce and separation are higher for females than males as men will find it easier to re-partner or will have died since the divorce or separation took place. Overall, the reporting of marital status in the RPHC5 is also consistent with the levels and patterns observed in the 2012 census. In general, there is enough evidence that the basic data obtained on marital status is credible and of high quality

Table7. 15: Distribution (%) of the resident population aged 12 years and above by current marital status by Sex

| Marital status | Male | | Female | | Both sexes | |
|--|------------------|------------|------------------|--------------|------------------|--------------|
| | Count | % | Count | % | Count | % |
| Married to one wife/husband officially | 1,406,723 | 31.8 | 1,472,987 | 30.6 | 2,879,710 | 31.2 |
| Married to one wife/husband not officially | 740,036 | 16.7 | 817,747 | 17.0 | 1,557,783 | 16.9 |
| Live in a polygamous | 31,453 | 0.7 | 66,691 | 1.4 | 98,144 | 1.1 |
| Divorced | 5,307 | 0.1 | 13,293 | 0.3 | 18,600 | 0.2 |
| Separated | 39,889 | 0.9 | 114,502 | 2.4 | 154,391 | 1.7 |

Source: Fifth Rwanda Population and Housing Census, NISR (2022).

7.4.2 Migration

Along with fertility and mortality, migration is one of the three components of population change and a key demographic variable that affects several other important outcomes such as health, economy, labour force, and brain drain or brain gain, among others (Adepoju, 2011; Fisher *et al*, 2021; Holmes *et al*, 2021). Levels and patterns of migration is measured in the 2022 census and Table7. 16 presents the distribution of recent migrant population. The results indicate there are 889 thousand recent migrants, with City of Kigali having the largest in-flow of migrants (around one-third, i.e., 354,970), followed by the East (306,091), South (109,488), North (72,841) and West (45,783). These results are consistent with those reported in 2012 Census which

also indicates strong migration flows out of the South and West, and strong flows into the City of Kigali and Eastern Province. The large flows of recent migrants into these two provinces may be explained by the fact that City of Kigali is Rwanda's capital city while East is experiencing growth as a result of the availability of lands in the province. The levels and patterns of migration flows observed in the 2022 Census follows the expected trend and pattern. They are also consistent with other data sources such as the 2012 census. There is reasonable evidence to suggest that the basic migration data obtained in the 2022 Census is of high quality.

Table7. 16: Distribution (count) of the recent migrant population (in the preceding 5 years before census, both sexes)

| Province of previous residence | Province of residence (Destination) | | | | | Outmigrant |
|--------------------------------|-------------------------------------|----------------|---------------|---------------|----------------|----------------|
| | City of Kigali | South | West | North | East | |
| City of Kigali | 146,452 | 47,402 | 13,832 | 25,716 | 93,663 | 180,613 |
| South | 140,755 | 102,895 | 13,207 | 10,482 | 68,067 | 232,511 |
| West | 88,282 | 37,177 | 66,033 | 23,905 | 68,081 | 217,445 |
| North | 47,504 | 8,718 | 9,703 | 29,055 | 76,280 | 142,205 |
| East | 78,429 | 16,191 | 9,041 | 12,738 | 146,547 | 116,399 |
| Not stated | 595 | 370 | 482 | 372 | 954 | 2,773 |
| In-migrant | 354,970 | 109,488 | 45,783 | 72,841 | 306,091 | |

This table include Rwanda native and foreign born

Notes: (1) A recent migrant is defined as an individual that lives in a different district than the district where he/she lived five years ago. The above table presents information at the provincial level, please note that recent migrants that have moved to another district may still be residing in the same province.

7.4.3 Quality of Economic Activity and Labour Force Data

Data on economic activity and labour force participation is very critical for economic planning of a country. Rwanda started using the new international standard on work, employment, and underutilisation in 2016. These standards are being implemented in the quarterly labour force survey for which data collection is carried out in February, May, August and November of each year. During the 2022 census enumeration, the data collection for quarter three of the labour force survey was also ongoing. The fact that the labour force survey was conducted at the same time as the census gives a strong ground for assessing the quality of census data using the labour force survey for the comparable questions.

7.4.3.1 Employment

Even though the questions to identify employed persons in the census were not as detailed as in the labour force survey, the results on the employment-to-population ratio were almost the same at the national level. According to the results in Table 7.17, the employment-to-population ratio is 0.5 percentage points lower in census than in labour force, which falls in the confidence interval of the labour force data.

Table 7.17: Comparison of employment to population ratio from labour force and census data

| Province | Labour force Survey, August 2022 | | | PHC August 2022 | | |
|-------------------|----------------------------------|--------|-------|-----------------|--------|-------|
| | Male | Female | Total | Male | Female | Total |
| Kigali city | 63.5 | 47.3 | 55.4 | 65.6 | 45.0 | 55.4 |
| Southern Province | 53.7 | 36.7 | 44.8 | 49.0 | 37.6 | 42.9 |
| Western Province | 52.2 | 34.0 | 42.3 | 47.9 | 37.6 | 42.3 |
| Northern Province | 56.1 | 42.3 | 48.5 | 48.3 | 38.2 | 42.9 |
| Eastern Province | 55.0 | 35.5 | 44.7 | 53.2 | 43.2 | 47.9 |
| Total | 55.5 | 38.2 | 46.4 | 52.4 | 40.2 | 45.9 |

Source: Fifth Rwanda Population and Housing Census, (2022), Rwanda Labor Force Survey quarter 3 (August 2022) NISR

The breakdown of employment by economic activities (Table 7.18) reveals that the structure/distribution of economic activities is the same for the census and the labour force but the employment in agriculture activities is over reported in the census on one hand, and activities in construction and manufacturing are under reported also in the census on the other hand. It is important to note that the under-reported activities are often practised in parallel with agriculture, especially in rural areas. This implies the possibility that respondents reported the usually practised activities instead of paying attention to the ones carried out in the reference period.

Table 7. 18: Distribution of employed persons by main economic activity in labour force survey and census.

| ISIC High level | Labour force survey , August 2022 | | | Population Census 2022 | | |
|---|-----------------------------------|--------|-------|------------------------|--------|-------|
| | Male | Female | Total | Male | Female | Total |
| Agriculture forestry and fishing | 38.5 | 54.7 | 45.6 | 44.3 | 63.9 | 53.4 |
| Mining and quarrying | 1.9 | 0.8 | 1.4 | 2.3 | 0.3 | 1.4 |

Source: Fifth Rwanda Population and Housing Census,(2022), Rwanda Labor Force Survey quarter 3 (August 2022) NISR

Results of assessment from triangulating the census and labour force data offer some lessons for future census enumeration. First, the design of the module on employment in the Census questionnaire must follow the UN guidelines for measuring the economic activity in a population and housing census. Second, during enumerators' training for future censuses, it is important to give a thorough training and make clear emphases on economic activities such as construction works which serve as alternatives to agriculture, particularly among the rural residents. Third, as it is done in the labour force surveys, future census enumerations should consider identifying employment in agriculture using two steps – (i) identifying all persons engaged in agriculture, and (ii) using a follow-up

question to separate them on the destination or use of the product from the agriculture.

The comparison of the institutional sector in the labour force survey and population census as indicated in Table 7.22, shows a high similarity in the distribution from both sources. However, for the status in employment, despite the same structure in the distribution from both sources, the proportion of employees in the census seems to be underestimated compared to the labour force survey (Table 7. 20). One possible reason may be the displacement of some alternative activities to agriculture like construction whose 'status in employment' often is "employee" compared to people in agriculture whose 'status in employment' is mainly "self-employment".

Table7. 19:Distribution of employed persons by institutional sector in the labour force survey and census

| Institutional sector | Labour force survey(August 2022) | | | Population census(August 2022) | | |
|-----------------------------------|----------------------------------|--------|-------|--------------------------------|--------|-------|
| | Male | Female | Total | Male | Female | Total |

7.4.3.2 Unemployment

In the census and labour force survey, an unemployed person is identified using three questions. There is not much difference in the proportion of persons without employment in the labour force and the census (53.6% and 55.0% respectively). However, significant differences appear in the answers provided to the questions posed to people actively looking for a paid job. While the proportion of the eligible population who affirmatively responded to this question from the labour force is 18.8%, it is only 7.7% in the census. This difference resulted in a big discrepancy between the unemployment rates of both census and labour force survey. The possible reason for the observed disparity is the respondents' wrong interpretation of the concept of "paid job" arising from the enumerators' inability to provide detailed explanations on the concept. Another

possible reason for the discrepancy may be due to the complexity of the concept of a "paid job" and a "profit job" as indicated in the question. If not clearly asked, the respondent may respond negatively referring to one concept instead of the other with the opposite response. In future censuses, it is recommended to conduct a series of cognitive tests among enumerators on such complex questions and concepts. Appropriate probing techniques should be employed during the training to ensure adequate comprehension of concepts among the enumerators. Besides, Pilot Census could be used during future enumeration to assess the understanding of respondents on such complex questions and concepts. More importantly, future enumerations should consider simplifying difficult questions using relevant probing questions.

7.4.4 Education

Education is an important characteristic for measuring a country's human capital development (Shani, 2020). Therefore, high-quality reporting of a country's basic and higher levels of education is critical for setting appropriate national priorities. It also serves to identify gaps and to guide the framing of educational programmes and interventions, where necessary. Hence, there is a need to ascertain the quality of reporting on education as measured in the census. Table 7.21 presents the distribution of the population aged 15 years and above by language(s) of literacy. The result shows that slightly more than half of Rwandan population are literate in Kinyarwanda only. This pattern is consistent across all provinces, except in City of Kigali where less than half (46.5%) of the population are literate in Kinyarwanda only. This pattern is expected as higher rates of educational attainment is associated with higher level of literacy in languages other than one's local language. City of Kigali has the highest proportion

of educated population in the country; hence it also has the highest percentage (21.6%) of people with literacy in Kinyarwanda and English languages.

The percentage of the population who never attended school in Rwanda is 22.3 percent (Table 7.21), with slightly higher proportion among females (23.4%) compared to males (21.1%), thus showing the expected pattern of higher educational attainment among the male population relative to females. The rural-urban distribution also shows the expected pattern of higher percentage of people who never attended school in rural communities (24.0%) compared to urban areas (18.0%), thereby demonstrating high confidence in the reported basic data on education. It is, however, important to note that 3.2% of the households needed to have the information they reported on 'never attended school' changed to 'currently attending school' due to inconsistencies in reporting (see Annex B)

Table 7.21: Distribution of the population aged 15 years and above by language(s) of literacy and by province⁹

| Language of Literacy | Province | | | | | |
|--|-----------|----------------|-----------|-----------|-----------|-----------|

7.4.5 Life Expectancy

Life expectancy is an important indicator of health and wellbeing and a critical index of development that is used to evaluate the progress of a country's human development index (Echevarria & Iza, 2006). There is therefore the need to assess the life expectancies generated from the reported mortality data and the life table parameters adopted, to confirm whether the numbers are plausible. Figure 7.13 shows the trend in life expectancy at birth over a period of 44 years (1978-2022). The life expectancy at birth increased from 46 to 54 years between 1978 and 1991. It decreased from 54 to 51 years between 1991 and 2002, and later increased to 64 years in 2012 and 69.6 years in 2022 according to the RPHC5. This trend and pattern align well with the history of Rwanda and reflects the impact of government programmes in the health sector as well as the general improvements in the socioeconomic wellbeing of the population. Figure 7.13 also shows the expected pattern of higher life expectancy at birth for females (71.2 years) relative to males (67.7 years), thereby indicating excess mortality among the former than the latter. Further, the life expectancy computed based on RPHC5 is close to the medium

scenario projection values based on the RPHC4 (68.2 years)¹⁰ and from the UN (67.1 years)¹¹. Although, assessment of mortality data in Section 7.3 indicates some evidence of underreporting of death at total population level, however, the indirect methods used appears to have yielded plausible estimates that are in tandem with current development and socio-economic reality in the country. Thus, there is strong evidence that life expectancy figures obtained from the RPHC5 are of high quality.

Figure 7. 13 Evolution of life expectancy at birth between 1978 and 2022 by sex

¹⁰ As reported in the main indicator report of the Fourth Rwanda Population and Housing Census, 2014 (NISR).

¹¹ UN Population Division (2022): World Population Prospects, <https://population.un.org/wpp/Download/Standard/CSV>.

CHAPTER 8: CONCLUSIONS AND LESSONS LEARNT FOR THE NEXT CENSUS

8.1. Census Operations And The Use Of Modern Technologies

A careful evaluation of the activities implemented during the pre-enumeration, enumeration, and post-enumeration phases of the RPHC5 indicates a rigorously planned and well executed processes carefully managed by the NISR to maximise the data quality both with respect to the measurement of the population's attributes and its representation within the final database. Although, during parts of the pre-enumeration phase in 2020, there were challenges regarding the restriction of movement following the outbreak of COVID-19 pandemic, nevertheless, reports obtained on the census operation indicate that the pilot census was carefully planned and well implemented to effectively test different aspects of census operations, including the questionnaire development, training of enumerators and fieldwork management processes. The lessons learnt from the pilot census were carefully used to refine the entire components of the census operation. This largely contributed to the quality of data from the census. Importantly, the use of modern technologies at

different stages of the census operation, as recommended by the UN, considerably enhanced the overall quality of the RPHC5. The use of hand-held devices (mobile phones) introduced stringent quality control measures and checks during the enumeration. It also eliminated the need for daunting post-enumeration activities like data entry and coding. Further, a comparison of data imputation reports for the two most recent censuses shows that efforts required at the editing and imputation phase had greatly reduced in the 2022 Census. There is a greater improvement regarding the number of variables needing imputation as well as the magnitude of data imputation done in the RPHC5 compared to RPHC4. The use of modern technologies also greatly reduced the turnaround time for data analysis and report writing. There is good evidence that the use of modern technologies eliminated several data quality issues that may have arisen from the use of PAPI and manual data processing, thereby ensuring a high quality of the final database.

Lesson: There is a need to continue ensuring more rigorous planning and implementation of pilot census for future censuses. Despite analysing the pilot census data, some limitations were identified in the responses to some questions on economic activity. Based on the role played by enumerators as far as quality of data is concerned, it is recommended to conduct thorough trainings and a series of cognitive tests for enumerators for this end. In addition, appropriate probing techniques should also be employed during the training to ensure adequate comprehension of concepts among the enumerators.

8.2. Questionnaire Development

There was multi-sectoral collaboration in the planning and development of the questionnaire. This was done with the involvement of many relevant Government Ministries in the questionnaire planning to ensure the inclusion of relevant questions in the enumeration tools. Where possible, UN standard questions were used and were thoroughly pretested to ensure adaptation to

the local context of Rwanda. During the data editing and imputation phase, however, some data quality issues were identified with regards to a few questions, such as those on economic activities and school attendance. While a high number of households needed imputation for information on school attendance, responses to some questions on economic activity are of low quality.

Ensure that the analysis is more directly connected to questionnaire design from the start and attempt to complete all processes on the pilot census to ensure the questionnaire can be fully processed efficiently and deliver the data needed for relevant indicators and thematic analysis. While future enumeration exercise should consider simplifying difficult census questions, pilot census should be used to assess the understanding of both the enumerators and respondents on complex questions and concepts.

8.3. Recruitment And Training Of Enumerators

Apparently, there were quality issues that arose from the enumerators. It is well established that census enumeration requires a huge number of enumerators who may have varying aptitude and capacity for comprehension and ability to implement activities as trained. To some extent, the enumerators introduced some errors during the enumeration such as in the questions on economic activities and school attendance, despite the use of hand-held devices.

There is need for more stringent measures at the stage of recruiting fieldworkers to ensure that enumerators with high aptitude and capacity are recruited for the census.. In future censuses, it is recommended to conduct a series of cognitive tests for the enumerators. Appropriate probing techniques should also be employed during the training to ensure adequate comprehension of concepts by the enumerators.

8.4. Post-Enumeration Survey

The UN standard approach has been adopted with respect to the planning, conduct, and analysis of the PES. This is broadly based on the model developed for the PES by the US Census Bureau. It confirms the RPHC5 has a very high net coverage of 98.7% and the gross coverage error rate is 1.78% . Given the high estimated net coverage established by the PES, it is not recommended that any adjustment to the census database be contemplated based on the PES results.

Continue to use robust post-stratification approaches to ensure the future PES continues to yield reliable estimates of net coverage.

8.5. Age-Sex Data

Evaluation of age-sex data, as recommended by the UN, shows that there are some quality issues with respect to the reporting of age, nevertheless there are considerable improvements in the quality of age data in the RPHC5 when compared to the RPHC4. There is some evidence of age heaping and preference especially for ages with terminal digits 0 and 5. This evidence is clear in the population pyramid and line graph based on single years. However, summary measures from Whipple's, and Myers' indices as well as the UN joint

scores indicate comparatively some improvement and reduction in age heaping in 2022 Census compared to the 2012 Census. Overall, the issue of age heaping disappears in the population pyramid and line graph based on grouped age data, thus indicating that avoidance of an age in preference for another largely occurred within the same five-year age-group. There is therefore strong evidence that age heaping is not sufficient to negatively impact the data quality when analysing grouped age.

Continue to emphasise the importance of age-sex data during enumerator training to ensure that age reporting continues to improve in future censuses.

8.6. Fertility Data

There is strong evidence that the current births and lifetime fertility from the 2022 Census are of high quality. There is, however, some evidence of underreporting of births at the younger ages of mother, particularly ages 10-19. This is often the case for teen mothers in many censuses, nevertheless, with increasing median age at first birth in Rwanda, currently at 23 years, fertility level at younger ages is likely to be minimal. In this regard, a comparison of relevant fertility indicators for RPHC5 and other sources like the Demographic and Health Surveys (DHSs) shows a consistent pattern of fertility decline in the country. Independent fertility evaluation shows strong evidence of high quality of reporting for the current births and lifetime fertility. Thus, there would be no need for adjustment of fertility. However, evidence on the infant mortality rate as measured using the reported deaths in the fertility section indicates some underreporting of infant

mortality. ***Continue to emphasise the importance of the fertility data during enumerator training to ensure that its coverage of recent births does not decline in future censuses.***

8.7. Mortality Data

Under-reporting of death in the year before the census has been the consistent feature of the past censuses of Rwanda, as is often the case with many household-based mortality reporting in many countries. This necessitated the use of indirect techniques to derive the best attainable mortality estimates from the 2002 and 2012 Censuses. Evaluation of mortality data for the 2022

Census shows some improvement in the quality of death reporting compared to the past censuses. Nevertheless, underreporting of death persists in the 2022 Census. There is evidence of under-reporting of infant deaths and across other ages, hence, the use of indirect methods is recommended and used for estimating mortality rates.

To ensure improved reporting on mortality questions, there may be need to move the mortality section from the very end of the questionnaire to perhaps the middle of the questionnaire. Mortality is a difficult subject for enumeration due to socio-cultural reason, asking question on it towards the end of the enumeration interview when fatigue may have set in would further raise quality issues.

Strengthen the checking of the mortality data within the field by the monitors to ensure that the yes/no question has been completed.

Take advantage of the available restriction features in the electronic devices in CAPI and use proper in-built consistency checks and linkages towards ensuring that data such as recent deaths recorded in the fertility section are also reflected in the mortality section.

Consider using the local leaders as another quality check as they will likely have some knowledge of deaths that have occurred during the previous year.

Consider a specific follow-up survey, in addition to the PES, to just target the measurement of mortality. This could either be an independent check, as with the PES, or more dependent in nature with a sample of household being drawn from those enumerated by the census.

8.8. Socio-Economic Indicators

Key socio-economic variables considered for evaluation include marital status, migration, economic activity, education and life expectancy. Less comparisons are made for these subjects relative to key demographic variables like age, fertility and mortality. Evidence from the assessment done shows plausible numbers and high-quality of reporting for marital status, migration, education and life expectancy. However, as discussed earlier, data on some indicators on economic activity is of low quality.

Lesson: Ensure more thorough pilot census not only to properly pretest all questions in the census questionnaire, but also to process and analyse the pilot data and apply the lessons learnt to ensure a well-implemented census enumeration.

8.9. Concluding Remarks

All NISR teams involved in the planning and implementation of the RPHC5 are to be commended for meticulously undertaking such a daunting task with a relatively short turnaround time. Without mincing words, RPHC5 is of high quality. The overall impression is that the data quality both with respect to the measurement of the population's attributes and its representation within the final database are good. This is further supported by additional triangulation and inspection

of other key attributes in this report, as well as comprehensive analysis in the full set of thematic reports. Age-heaping is evident but minor, and the only significant weakness in the final database is with respect to the direct measurement of mortality.

ANNEX A : CENSUS QUESTIONNAIRE

This annex provides the full questionnaire of the Census questionnaires.

As mentioned above, two different types of questionnaires were administered, one for private households and one for institutional households. The questionnaire for private households contained a population record, a household record and a mortality record. The questionnaire for institutional households contained only a population record.

A.1 Private households: person record

Annex B: RPHC5 edit specifications (version December 2022)

General procedure:

1. Identifier must be unique
2. There must be at least one person in the household
3. There must be one household record for every household
4. Institutional household should not have Housing Record and death record
5. Range checks on all variables in all records
6. Universe checks on all variables in all records
7. Consistency checks pop
8. Consistency checks death
9. Consistency checks housing

| Variable | Specification (detect error) | Message | Method of correction of error | Denominator |
|----------------------------|---|---|--|---------------|
| QUESTIONNAIRE LEVEL | | | | |
| Various | Households Reported as Not interviewed | QUEST-01: Delete the Not interviewed cases. | Delete the Not interviewed Households | |
| Various | Empty Line in Records without Line Number | QUEST-02: if no Line Number ,delete that line. | if no Line Number, delete that line | |
| Various | Household status is not completed | QUEST-03:Delete all the data when the household status is not completed | Delete all the data when the household status is not completed | |
| Various | Set empty household as not visited | HH-01: Household with no household member | Impute with NHSTATUS = 6 | TotHH |
| POPULATION RECORD | | | | |
| P02 | Head must be at least 12 years | POP_REC-01: HH head has less than 12 years. | Make the eldest the head. | TotPrivatePop |
| P02 | Households without household head | POP_REC-03: No household head. | Keep the eldest as head. P02 = 1 | TotPrivateHH |
| P02 | More than one household head. | POP_REC-05: More than one hh head. | Keep the eldest head and impute others head with P02 = 11 | TotPrivateHH |
| P02 | The head of household is not a resident. | POP_REC-07: The head is not a resident. | Make the resident spouse as head. P02 = 1 | TotPrivateHH |
| P02 | Head is listed as Father but child is not the head's son | P02-01: Head is listed as Father but child is not the head's son. | Impute P02=3 | TotPrivatePop |
| P02 | Head is listed as Mother but child is not the head's son. | P02-02: Head is listed as Mother but child is not the head's son. | Impute P02=3 | TotPrivatePop |

| Variable | Specification (detect error) | Message | Method of correction of error | Denominator |
|----------|---|---|---|---------------|
| P02 | Age of spouse is less than 12 years. Relationship inconsistent with the marital status. | P02-03: Age of spouse is less than 12 years. Relationship inconsistent with the marital status. | Impute P02=11 | TotPrivatePop |
| P02 | More than one spouse for The Female head | P02-04: More than one spouse for The Female head . | Keep first spouse impute Others P02=11 | TotPrivatePop |
| P02 | More than one spouse and the head or none of the spouse is in polygamous union. | P02-05: more than one spouse and the head or none of the spouse is in polygamous union. | Keep first spouse ,impute Others P02=11 | TotPrivatePop |
| P02 | More than 2 parents in law of a Female head | P02-06: More than 2 parents in law of a Female head. | keep first Parent in law and Impute P02 = 11 for others | TotPrivatePop |
| P02 | More than 2 parents of head. | P02-07: More than 2 parents of head. | keep the first reported Parent and for others P02=11 | TotPrivatePop |
| P03 | Male having fertility data. | P03-02: Male having fertility data. | Impute P03 = 2 | TotPrivatePop |
| P03 | Head and Spouse have same sex. | P03-03: Head and Spouse have same sex. | Impute with opposite sex | TotPrivatePop |
| P04 | HH head is less than 12 years and no member greater than 12 years. | P04-04: HH head is less than 12 years and no member greater than 12 years. | Increase the head's age | TotPrivatePop |
| P04 | Age of child must be 15 years less than age of Head. | P04-05: Age of child must be 15 years less than age of Head. | Increase head's age | TotPrivatePop |
| P04 | Age of father in law must be greater than 30 years | P04-06: Age of Father in law must be > 30 years than age of Head. | Increase father in law age | TotPrivatePop |
| P04 | Age of mother in law must be greater than 24 years of age head | P04-07: Age of Mother in law must be > 24 years than age of Head. | Increase mother in law age | TotPrivatePop |
| P04 | Age of household head should be greater than 24 years age of grand child | P04-08: Age of grand child must be 24 years less than age of Head. | Increase age of Head | TotPrivatePop |

| Variable | Specification (detect error) | Message | Method of correction of error | Denominator |
|----------|---|--|------------------------------------|---------------|
| P04 | Age of parents must be 12/15years aolder than the head | P04-09: Age of parent's must be 12/15 years Older than head's age. | Increase Parent's age | TotPrivatePop |
| P04 | Age of spouse must be > 12 years | P04-10: Age of spouse is less than 12 years. | Impute P04=21 (legal marriage age) | TotPrivatePop |
| P05A | Invalid month of birth. | P05A-01: Invalid month of birth. | Impute P05A = 99 | TotPrivatePop |
| P05A | Unknow year of birth but know month of birth. | P05A-02: Unknow year of birth but know month of birth. | Impute P05A = 99 | TotPrivatePop |
| P05B | Invalid year of birth. | P05B-01: Invalid year of birth. | Impute P05B = 9999 | TotPrivatePop |
| P05B | Year of birth is 2022 and Month > 9(Month of Data collection). | P05B-02: Year of birth is 2022 and Month > 9(Month of Data collection). | Impute P05B = 2021 | TotPrivatePop |
| P06 | Spouse/head with spouse must be married. | P06-01: spouse/head with spouse must be married. | Impute P06 = notappl | TotPrivatePop |
| P06 | The head and spouse must have the same marital status | P06-02: The head and spouse must have the same marital status. | Impute P06 = notappl | TotPrivatePop |
| P06 | Age less than 12 years and responded marital status | P06-03: less than 12 years and responded marital status. | Impute P06 = notappl | TotPrivatePop |
| P06 | age < 18 years and officially married | P06-04: age below 18 years and officially married. | Impute P06 = 2 | TotPrivatePop |
| P06 | Head marital status when his spouse is aged below 18 years and officially married | P06-05: Correct the head marital status when his spouse is aged below 18 years and officially married. | Impute P06 = 2 | TotPrivatePop |
| P06 | Boys below 17 years and live in polygamous union | P06-06: Boys between 12 and 17 years and live in polygamous union. Enumerators errors. | Impute P06 = 6 | TotPrivatePop |
| P06 | Divorced below age 21 years | P06-07: Divorced below age 21 years. | Impute P06 = 5 (separated) | TotPrivatePop |

| Variable | Specification (detect error) | Message | Method of correction of error | Denominator |
